THE
ARCHITECT
AND CONTRACT REPORTER.
A JOURNAL OF ART, CIVIL ENGINEERING & BUILDING.

THE WEEK.

To-day the Workmen's Compensation Act comes into operation. There is no denying it is looked upon with alarm by employers, for its spirit can be expressed by saying that an employer is assumed to be guilty of some neglect whenever an accident occurs. One of the consequences is that, in self-protection, employers will be forced to dismiss old workmen and those who are awkward in their movements. Never was the law of the survival of the fittest so rigidly applied as it will be during the next six months. The interest which the Act excites is evident when we find Messrs. Minton-Senhouse and G. F. Emery, barristers-at-law, preparing a people's guide, which can be purchased for one penny from Bemrose & Sons, Limited. It is, we suppose, the cheapest legal treatise in existence. But the workmen have a superabundance of legal advisers at command, and we are afraid the new Act will give occasion to many a repetition of John Selden's exclamation, "Woe to the State where lawyers flourish."

Two years ago there was a fire at Sharpe's Wharf, Wapping, of which the Governors of Bridewell Hospital are the freeholders. The origin of the fire was ascribed to the erection of new boilers and a flue, partly against the wall of the warehouse and partly within it, by the occupants of the adjoining premises, which were used as soapworks. The heat of the flue set fire to a large wooden girder. The Governors declared that the wall was a party wall or structure, and therefore they should have received the notice prescribed in the Building Act. The cost of reinstating the premises (1,005*l.* 2*s.* 7*d.*) was claimed, together with 100*l.* damages for trespass. The defendants, Messrs. Paton & Charles, denied that the wall was a party structure, and also alleged that no effort was made to extinguish the fire on the part of the Governors or their tenants, and that more was done than reinstating the premises as they were before the fire, for that work need only have cost 550*l.*, which sum was lodged in Court. Mr. Justice Channell, who heard the case, decided there was no trespass committed, and that the action could only be maintained on the ground of damage to the reversion of the lessee. His lordship assessed that damage at 666*l.* The judgment is interesting as the defendants were not made liable for the cost of the improvements in the building, which were required by the provisions of the Act of 1894.

Temporary partnerships are sometimes arranged for carrying out engineering works, and in England there is no difficulty in dividing the profits. But a Canadian appeal case which came before the Judicial Committee of the Privy Council on Tuesday reveals that disputes can easily arise between the partners. In 1877 the late Simon Peters obtained a contract amounting to 529,296 dols., for the construction of a dock in Quebec. An extra work of 18,393 dols. was afterwards ordered. Mr. Peters entered into an arrangement with Messrs. Moore & Wright to do part of the work on the understanding that, while appearing as partners, each would be paid at contract price for whatever was done. Instalments were duly received, and when the dock was completed the Harbour Commissioners offered 52,011 dols. as the balance. The amount was considered insufficient, and the Courts afterwards awarded 87,468 dols. as the amount due. The partners could not agree about the proportion in which the money should be divided, and 68,972 dols. were lodged in bank. Litigation began, and in 1896 the Court held that as the agreement between the parties was not definite, the section of the Civil Code should be applied which affirms that when the shares of partners are not fixed, they must be considered to be of equal amount. On appeal it was decided that Mr. Peters's representatives should be paid 27,667 dols., the remainder becoming the property of Messrs. Moore & Wright, who were dissatisfied with the arrangement, and appealed to the Judicial Committee of the Privy Council. The decision was given against the appellants on most of the points raised, and they were ordered to pay three-fourths of the costs. The result is another instance of the risks which are incurred by indefiniteness in the language of deeds, for in this case it was evidently intended that neither party in the partnership should earn a dollar through the labours of the other.

M. Benjamin Constant, who is charged with the commission for the ceiling of the new Opéra Comique in Paris, has not only completed the studies and sketches, but has made some progress with the painting on the canvas. But with all his experience in the management of colours he has come to the conclusion that it would not be prudent to proceed further until he has made a trial of the effect of what he has already accomplished. For that purpose he proposes to have his canvas temporarily affixed to the ceiling of one of the theatres which has closed its doors until the end of autumn, when the theatrical season commences. Then when he sees his work illuminated by the electric light he will be able to realise what modifications are necessary to produce the full effect. The artist in painting has made allowances for the difference between daylight and artificial light, and he is eager to assure himself that he has done enough to satisfy spectators when they see his *plafond* from various points of view in the theatre.

The Opéra Comique was destroyed by fire on May 27, 1887, when nearly 100 people who were present at the performance of "Mignon" lost their lives. An action was taken against the lessee, two firemen, a machinist, and the official architect. They were acquitted in both the courts where they appeared. Several children were left destitute by the death of both parents who were among the victims. Their guardians endeavoured to obtain a little compensation for them by suing the State as a defendant. But the case went against them, and the utmost concession that was allowed was to refrain from demanding the costs, amounting to about 600*l.*, which the judges had ordered the plaintiffs to pay. Among the claimants were the guardians of the children of an Austrian banker, and they resolved to continue the process from court to court. The Tribunal of the Seine decided that the State could not be made a party to a civil action. But last week the Cour de Paris held that the State took the place of an ordinary proprietor of a theatre, and must be responsible for compensation. A decree for the payment of 4,000*l.* was given, with interest at the rate of 5 per cent. for the time which has elapsed since the claim was made.

42503

THE ORCHARD STREET CASE.

AFTER the inquest on the victims who were killed by the fall of the building in Orchard Street, Westminster, we expressed a doubt whether any jury directed by one of the judges of the High Court would endorse the finding of the coroner's jury.* That finding was as follows:—"The deceased met their deaths through injuries received by the collapse of a portion of the south block of Abbey Mansions. The cause of the collapse was owing to the faulty design and construction of the pier due to the culpable negligence of the architect. The jury are of opinion that some of the concrete in the roof was carelessly mixed and irregular in quality, but it was not the initial cause of the collapse." The points to which we took exception were, first, that sufficient importance was not attached to the removal of the centring, which was followed by the inevitable descent of the concrete roof. The initial cause of the catastrophe arose in that way. We also pointed out that although an array of specialists attended the inquest, not one of them was asked, or attempted to express in plain figures, what a fall of so large a mass of solid materials signified as a destructive agency. Mr. Justice GRANTHAM took a similar view. "The primary cause of the accident," said his lordship, "was clearly the removing of the centring from the concrete. A crash is heard and down goes the roof to the girder below. That fell on to the girder on the next floor. The weight of the falling mass would be increased as it fell, and so it goes down with increasing weight." We also explained how authorities differed about the weight which a brick pier or, rather, a column, should sustain, for in experiments a column rather than an attached pier is subjected to the crushing weights, and there was no justification of the theory that to the faulty design and construction of the pier the loss of life must be attributed. Mr. Justice GRANTHAM said there was "no evidence whatsoever that the cause of the accident was the collapse of the pier." It is hard on the Superintending Architect of the County Council that his elaborate disquisition on the construction should not be regarded as evidence, but the word has a meaning in the mind of a lawyer which differs from that accepted in Spring Gardens. Once admit, as the judge said, that "the real cause of the accident was the removing of the centring from the concrete, and it would be most unfair to ask anyone to find the prisoner guilty." His lordship accordingly directed the jury to bring in a verdict of not guilty.

We have no wish to claim extraordinary prescience in our conclusions. They were simply those which must arise in the mind of any practical man who has had to take a part in building operations. That Mr. Justice GRANTHAM should have arrived at the same end by the guidance of the laws of evidence alone—for his lordship acknowledged that at first he did not understand the importance of centring in concrete—is creditable to his lordship's acumen and impartiality. Architects and others who are acquainted with the mysteries of construction took a different side, and for a time DISRAELI's proposition about hanging an architect as the only means to insure sound building in London appeared to be concentrated wisdom worthy of an oracle.

We have no desire to hold up the disorganisation which, according to the evidence, prevailed in Abbey Mansions as worthy of imitation in other places. There was enough brought forward to demonstrate that chaos had come again, and that latter-day building, although inspired by science, was a revolt against common sense. All the co-operation was independent. Directions might be given, but there was nobody with sufficient power to see they were carried out. The man who, in ordinary circumstances would be considered the builder had to be content with an occasional glance at the labourers. If anything provided was inadequate, nobody would take the trouble to have it remedied. Witnesses differed about the simplest facts, which was not surprising when we remember the general indifference which prevailed. The working drawings were worthless, for they did not come into existence until after the catastrophe. The whole of the operations were, however, of the kind which might be expected with an architect who declared he was trained in the South Kensington School of the Science and Art Department. There was also a mystery about the source whence the money was derived, and the complications are so numerous it is likely the relatives of the victims will not be able to attach responsibility to any individual. Taken altogether, the case is one which is enough to make all lovers of English building mourn for the decadence into which we have fallen.

But if the wrongdoers merit punishment it is only fair to them that their prosecution should be equitable throughout. In the case of the architect the early proceedings were as unlike the ordinary English course of law as the works were unlike an ordinary English builder's. The procedure began with a letter from one of the workmen to one of the County Council, in which it was said that the pier was made up of soft bricks and mortar. The County Council could not neglect the opportunity of making capital out of the occasion and posing as the champions of the martyrs of industry. The inquest consequently became a sort of state trial of an enemy of the people, a second STRAFFORD. With the letter before them the jurymen were convinced of the cause of the collapse before any evidence was heard, and had all the Council of the Institution of Civil Engineers declared that if the concrete arches of the roof were allowed time to consolidate the building would still be standing, the jurymen's finding would be unaltered. With such men as are usually placed on coroner's juries, prejudice cannot be easily overcome. The workman's statement was declared to be false by the judge, but it is still accepted in Westminster as the solution of the case. So much is said about the virtues of operatives by their flatterers, we must not be surprised if the men are strong in the belief of their immunity from error. The blame for all accidents is left on those who are in authority. The feeling will have its effect in the working of the new Compensation Act, for when the men employed on works are biassed we cannot expect them to become suddenly impartial, and to testify that an accident was caused wholly or partially by the negligence of the sufferer.

The moral to be drawn from the case is that the old-fashioned system of employing trained, experienced and responsible builders for the erection of mansions in Westminster and elsewhere is not obsolete, and should be adopted by building owners in their own interests. The workmen, however, prefer the haphazard mode which was employed in Orchard Street until seven of their representatives were sacrified to the assertion of their liberty. The time had not arrived for the removal of the centres, but those connected with that part of the edifice were of a different opinion, and they maintained their rights to act as they pleased. The County Council upheld their independence of authority, and preferred the theory that bad bricks and mortar, for which London workmen could not be held responsible, were the real factors in the tragedy, and that the architect should pay the penalty for their failure.

The remedy which the jury proposed to prevent a recurrence of such disasters was "a greater amount of public control." But it cannot be expected that a district surveyor or one of his assistants is to examine every load of bricks that is brought on a building site and every bag of cement, or is to be present at the laying of every joist or the removal of every prop. The interference of authority in building cannot be expected to be more constant than is allowed in other businesses. No doubt it is a misfortune that the funds for the erection of buildings are now often supplied by investors who may know nothing about the quality of the work which is performed for them, and are indifferent as long as dividends are paid. Perhaps a greater misfortune is that buildings are entrusted to the charge of men who claim to be competent because they attended "the Government School of Architecture at South Kensington" but as the character of that wonderful institution should be universally known by this time, people who lose over such buildings as Abbey Mansions are not to be pitied, and it would be absurd to protect them in building when they are allowed to impoverish themselves by other ventures. If competent architects and competent builders are employed and fair prices are given there is no need for any additional exercise of authority, but if checks must be imposed let the building workmen and the authorities who back them in their carelessness be selected for the experiments.

* See *The Architect*, June 3, 1898.

LA ROCHELLE.

By John A. Randolph.

OFF the beaten tracks of tourists, and almost as unknown to them as Luçon, or the quaint little town of Richelieu, lovers of the picturesque and of the architecturally and historically interesting will find much to reward them for the extra time and expenditure incurred in travelling, from the main touring lines, to La Rochelle; and forty eight hours or more can be profitably spent in investigating what the town possesses in the way of vestiges of the Middle Ages, and in sketching dainty nick-nacks of architecture or ornamental carvings and ironwork.

In the limited space at our disposal we shall try to point out some of the noteworthy features, both Gothic and Renaissance, which still remain to tell us of the architectural splendour which greeted the sight of Cardinal Richelieu and his retinue at the end of that memorable siege in which this country played so important a part.

Close to the town, the train passes through a charming and wooded suburb, which comes as a welcome relief after the flat and barren plains that extend from well-nigh Nantes to well to the south of this town—a barrenness all the more striking for want of any salient architectural feature, barring Luçon Cathedral and the church of Bressuire (near La Roche sur Yon), to relieve the dreary monotony of the fatiguing journey. To the eastward, however, the landscape is more undulating, and, architecturally, more interesting; but our route lay, for the nonce, from Nantes, and the approach to the sea was signalised by a decided change of atmosphere and sky as well as a change of landscape; fields giving way to dunes, or sand hills, such as skirt the Belgian coast from Heyst, and extend as far Francewards as Boulogne and Etaples.

The station at La Rochelle is an awkwardly planned terminus, and one is landed on the wrong side of the building, and has to walk round the train to get to the 'busses, which await the passengers. It is well to use those conveyances to the hotels on a first visit to the town, as the routes to those necessary establishments are generally erratic (especially so at Rennes) and the extra-large-sized cobbles very trying.

As soon as the 'bus clears the station, it passes under a double triumphal arch of fairly good design, battlemented and medallioned—the Porte St. Nicolas—a modern construction, and suggestive of antiquities "within the walls."

Skirting the docks and harbour on the left, church towers and turrets of divers sorts abound on all sides, and, strange to say, actually in the street, at some little distance to the right as the 'bus turns to the left, a small lighthouse is visible. Its light is in a line with the entrance to the harbour, which is on the left on leaving the station.

A short drive alongside the harbour quay, and the route into the town proper takes the traveller under the great Porte de l'Horloge, a few yards up the street. It is a Gothic edifice, with Renaissance superstructure, very pleasing in design and imposing in effect. From this point the approach to the hotel is of exceeding interest, parts of the street having arcading, both plain and ornamental, chiefly of the Renaissance period, but occasionally of the Gothic style. The curious feature of this arcading is that it is—to use an appropriate word—fitful. For yards there may be none at all, and then perhaps about a dozen houses or more will have some very fine examples, on one side of the street, while on the other side nearly the whole length is arcaded. The by-streets, small and irregular, sometimes contain arcading, but chiefly timber-framed fronts, something like those to be seen at Lisieux, Angers, and Nantes, but on a simpler scale of ornamental carving, which many will probably prefer. We do not remember to have found in so small a place so many timber houses, and fortunately for art's sake there is very little, if any, of the modernising process going on in the town. It is an old-world settlement, quiet and dignified, and has not even yet numerically recovered from the awful famine and slaughter caused by the siege.

Several of the houses in this thoroughfare have historical associations or associations with historic people, and doorways and chimney-pieces and other ancient fragments abound, even in houses of a very simple exterior. The restaurant entrance to our hotel just off the Place d'Armes, alongside the Musée, is a charming and well-preserved example of the middle of the seventeenth century—the date is still on it—and it struck us as having probably served as a model for the doorway that used to serve as entrance to the London School Board Offices previous to their completion.

Of course, the main attraction of La Rochelle, architecturally speaking, is the Town Hall, with its Gothic court wall battlemented and pierced with a large and a small canopied doorway (like those of the Hôtel de Cluny at Paris), its graceful circular Gothic turret—it is hardly a tower—with octagonal top, its truly sumptuous Renaissance frontage to the court yard and its exquisite balcony at the rear. Inside is beautiful wainscoting and the historic table which the Mayor pierced with his dagger when vowing that the enemy would have to trample over his body at the gates before they entered the town.

At one corner of the Place d'Armes is a large plain church, locally known as the Cathedral. It is Renaissance, and externally is imposing enough, but internally most unsatisfactory, the only objects of interest being the *ex-voto* pictures offered by the fishermen in recognition of safety from drowning or shipwreck. These pictures are chiefly modern, and of anything but good draughtsmanship, but the older ones show "impossible ships in impossible seas composed of impossible waves." The stained-glass in the church and the fittings are terrifying in their crudeness and ugliness. Outside the choir end, however, of this huge church, and detached from it, is the beautiful fourteenth-century tower of St. Barthelémy, at a corner of which shafts and their capitals are still visible which served to support one of the nave arches.

The Place d'Armes is the site of the old royal castle, demolished by the Rochelais in 1372, at the instigation of Mayor Chauldrier, when the English were made to leave it by false pretences, to be instantly occupied by the garrison of the town. The Museum off the Place d'Armes should also be attractive to the visitor. The library connected with it has about 45,000 books, many of which formerly belonged to the Rochelle Academy and to the Oratory of the town. Several sixteenth, seventeenth and eighteenth-century historical books are there, and nearly 1,000 MSS., some of which are illuminated. In the Museum is a painting of Richelieu and his retinue inspecting the defences of the celebrated Digue.

The guide-books say that the bishop's palace contains the chalice used by the Cardinal at Mass on November 1, 1628 (after the end of the siege), in the now demolished church of Ste Marguerite; but on inquiry there, in the hopes of seeing it, we were informed that the statement was erroneous. The Auffrédi Hospital was founded in 1203, when the town was developing itself. Its site is now occupied by the Hôpital Militaire, which bears a commemorative inscription.

Between the Town Hall and the harbour is another simple but lofty Gothic tower, belonging to the church of St. Sauveur. Close to is a fine fifteenth-century timber-framed house. Besides the churches and towers and arcading, some fine Gothic vaults or cellars are dotted here and there about the town, especially at 11 Rue St. Nicolas, where is also a magnificent chimneypiece representing the Sacrifice of Abraham; 3 Rue des Merciers is Mayor Guiton's house—the man who vowed the enemy would have to walk over his body; and 11 Rue des Augustins, the splendid house of Henri II., or, as locally known, of the ubiquitous Diane de Poitiers. It has several fine statues on its front, and dates from 1555. There used to be seven gates to the old fortifications, of which the Porte de l'Horloge was one. The St. Nicolas tower, which defended the harbour, and dates from 1384, still stands, but has recently been restored. The other two towers of the harbour deserve attention—the Martello, a squat, round, plain structure, and the Tour de la Lanterne (1445-76), cylindrical in shape, with seven floors, two side turrets, and a stone octagonal crocketed spire and pierced parapet. It was formerly a lighthouse.

A pleasant semi-countrified drive through Laleu, where Louis XIII. and Richelieu slept during the siege, may be taken from the Place d'Armes to La Pallice, the new port of La Rochelle.

The remains of the famous Digue are only visible at low water, and are close to the Bains Richelieu, at the extremity of the "gardens" to the left of the road to Laleu from the Place d'Armes.

Near La Rochelle is the curious fortified church of Esnandes, formerly surrounded by a moat. It dates from the twelfth century, and the central of the three west doors has Romanesque carving. The building is a *monument historique*, kept in repair at the expense of the country.

From La Pallice is a regular service of steamers to St. Nazaire and the South of England, and there is also one to Liverpool.

WAXEN IMAGES.

WORKS of art in wax suggest collections of imitations of fruit under glass shades which are prepared for the adornment of houses where a fine taste does not prevail. Small figures in wax are occasionally to be seen in museums, and surprise is expressed at the large sums which had to be paid for them. Portraits in wax on a miniature scale are to be found in the Salon and other foreign exhibitions. But in general wax is not a material which finds much favour with amateurs. From its pliability it is supposed to be easy to work, and a high price for an example appears to be an imposition, while the ease with which it melts causes a work for which it has been used to become a source of anxiety. A modern amateur must, therefore, be puzzled when he hears of the extensive use of wax among the ancients. It seems to be incredible that wax was used not only for portraits which were intended for preservation in order to uphold the reputation of a man among his descendants, but also for wills and documents which were to be the titles to estates, so much so that the word *cera* became another term for page, sheet, or folio, in deeds. The *tabulae ceratae* had, it is true, a foundation of wood, and precautions were taken to keep the surface from injury, as in the case of diptychs. But the fact remains that the covenants of legal deeds were inscribed on what is to us an evanescent material. When the poet in "Timon of Athens" talks of "a wide sea of wax" for his forthcoming work, we naturally think of praises which are inspired by the necessity of the moment, but to a Greek or Roman the phrase might mean a sort of immortality. They would be satisfied with such fame as could be conferred by the stylus of an able hand on wax.

It was not only in tablets wax was employed. It was an ingredient in paints and served instead of oil. To paint with wax, *ceris pingere*, signified the production of forms which were more brilliant than was possible with distemper. It is supposed heat was employed to bring out the full effect of the material, but although both VITRUVIUS and PLINY have left an account of the process, what they say is not sufficient to produce successful results. Another use of wax was to impart a peculiar velvety surface to marble statues, and to diminish the crystalline appearance of the material. In this case also we must suppose there was a dexterity in the application which is beyond the power of a modern sculptor.

The most remarkable use of wax was in the preparation of the ancestral images which were at one time the glory of a Roman house. The satisfaction of a collection of family portraits is as strong as ever among us. Time has condoned the misdeeds of the subjects. Unjust judges, rapacious placemen, stupid generals, or even "bishops who had not left a single sermon," attain some value as evidence of respectability. If portraits are not forthcoming by inheritance, Wardour Street can supply substitutes at reasonable rates. Whether the antique Romans in wax were always authentic representatives of the men whose names were attached to them cannot now be determined. Both MARTIAL and JUVENAL had their doubts on the subject, but contemporary writers who claimed to be also guardians of public morals considered the wax figures were not only signs of respectability but aids to the encouragement of virtue. There is little doubt the practice of preserving images was directly suggested by the honours paid to the Egyptian mummies, but it may also have been a survival of the ancient ancestral worship which is still practised with fervour by the Chinese. Whatever was their origin, the family images in the *armaria* of the *atrium* almost rivalled the household gods in their hold on the reverence of a household, and of course the oldest and dingiest examples were held in most esteem. Mrs. JARLEY would not be likely, however, to value them at a high rate. For a long time the privilege to possess waxen images of forefathers was restricted to the patricians, and they could only exercise it after serving as consul, ædile, prætor, &c. But when the plebeians became eligible to be seated in the curule chairs they could no longer be supposed to belong to a race without ancestors. The people appear to have had a voice in the matter, and as they at all times were endowed with far-reaching memories, a patrician's sins were fatal to his own chance of a highly-coloured portrait and to the distinguishing of his family. That the waxen portraits were sometimes prepared while the subjects were living is evident from the circumstance that one of the consequences of a crime against the State was the destruction of the culprit's image by his family. It was a sort of symbolic refusal to him of the respect of posterity. On some occasions the images were withdrawn from the *armaria* and carried in procession through the streets by relatives. On such occasions similar robes of office to those which were worn when living were set up on the images. Some archæologists believe that in the processions, instead of draped figures which were carried, portrait masks of the deceased worthies were placed over men's faces just as the tragic or comic masks were worn on the stage, and in that way a more vivid spectacle was secured. There is no improbability in the theory, for "making up" in imitation of particular individuals was practised among the ancients to an extent that would not be tolerated in a Paris *revue*.

The Romans were not able to preserve the effigies of their fathers under glass shades with so much success as, unhappily, awaits wax fruits and flowers. As there was a custodian for the *armaria* in all well-regulated houses, he would, we suppose, be able to patch and colour over defects, or, when required, to make reproductions. The *atriensis* was likely to have some acquaintance with various processes of the arts, for they were so largely employed as adjuncts to luxury, there must have been restorers of various classes who could make themselves useful whenever accidents occurred. The waxen images would not be huddled together in a corner of the *atrium*; they were too valuable to be neglected like the old portraits which in a modern house are often relegated to an attic. We may assume they were placed like images in Italian churches, and that wreaths and flowers were placed near them, with the inscriptions and eulogies which from time to time were inspired by the man's deeds. They were not objects of worship, but of affectionate respect. Many a Roman gentleman could perhaps say with Sir LUCIUS O'TRIGGER, "Though the mansion-house and dirty acres have slipped through my fingers, I thank heaven our honour and the family pictures are as fresh as ever."

The State appears to have aided the Roman O'TRIGGERS in preserving ancestral memories in spite of the vicissitudes of fortune. An old house might change hands, but the trophies of the old owners had to be respected. The houses, as PLINY says, always triumphed over Fate, and became a rebuke to those new proprietors who thought that wealth could take the place of courage and virtue. Whether the images of the former owners had to be taken over with the tokens of foreign conquests and patriotism is not known. But when we learn that VARRO published the lives of 700 of the illustrious men of Rome and other countries with their portraits, it is allowable to conclude that although imagination might be exercised with the faces of foreigners, for the counterfeit presentments of the old Romans there must have been some materials which at least had tradition to give them value. As works of art waxen images are generally without value, and the ancient examples could hardly be of a higher character. But with such a material there is a necessity for more fidelity to nature than is required with portraiture in stone or wood. VARRO was too grand a Roman to neglect any means which would insure correct likenesses of the old citizens, and he would not have attempted portraits if they were no more than exercises of the fancy of artists.

What kind of reproductions were employed by VARRO must remain a subject for speculation. WINCKELMANN supposed the copies were reliefs in plaster on a small scale,

resembling casts of coins and medals. But that would hardly be a creation which was described as sufficient to excite the envy of the gods. We may, however, conclude they were not full-size copies of the figures, busts or masks in wax, although originals of the kind may have been used from which to make copies.

GABLE OF "MAISON DES BATELIERS," OR "FOUR WINDS," ANTWERP.

THE HISTORY OF ATHENS.

THE subjoined address was recently delivered from the steps of the Parthenon by the acting director of the American School in Athens to a party of his countrymen :—

According to Thucydides, Attica consisted originally of twelve scattered towns. To his period undoubtedly belong the remains of the prehistoric palace and walls on the Acropolis, which correspond closely to the palace and walls of Tiryns, and which are generally identified with the "goodly house of Erechtheus," mentioned by Homer. The legendary hero, Theseus, combined these scattered settlements into one political organism, and with him Athenian history really begins. After the reign of a long line of semi-mythical kings, we have recorded a long struggle between nobles and commons, which finally resulted in the legislation of Solon and the establishment of a sort of democracy based upon revolt. This took place in 594 B.C. But hardly was the democracy established when it was subverted by Peisistratus, who maintained his power over forty years and was the first great builder. To him we owe not only the collection and collaboration of the Homeric poems, the establishment of the great Panathenaic festival, and the foundation of the Dionysiac celebrations—the origin of our modern theatre—but it was he who began the Temple of Olympian Zeus, who built the first great public fountain of Athens, the Enneacrounos, and supplied it with an aqueduct which can still be traced along the south side of the Acropolis and through the king's garden ; and who completed the old Temple of Athens, recently discovered by Dr. Dörpfeld, between the Parthenon and the Erechtheum.

Peisistratus died in 514, and was succeeded by his sons, Hippias and Hipparchus. Their reign lasted only four years, for in 570 Hipparchus was killed by Harmodius and Aristogeiton, the liberators of Athens and founders of true democracy. Hippias was driven into exile and retired to the court of the king of Persia, where he constantly endeavoured to incite that monarch to invade Greece.

Then came the Persian wars, with the great battles of Marathon and Salamis, the capture and sack of Athens, and finally the utter defeat of the Persian hosts on the plain of Platæa and in the waters of the Ægean, near Mycale, in Asia Minor. These victories were the real foundation of Athenian greatness. They were the inspiration of all her later achievements. With them begins a period of fifty years such as no other city can boast of, the period of Æschylus and Sophocles, of Pheidias and Polycleitus, of Herodotus and Thucydides.

At first, it must be admitted, the outlook was not encouraging. On their return to their homes in 479 B.C. the Athenians found a city in ruins, its temples burned and overthrown, its walls destroyed. Themistocles was the leading spirit of the times. It was under his influence that the wall of Athens was extended to the limits which it occupied throughout the classical period, extending about the city in a great circle, including the Hill of the Muses, the Pnyx, the Hill of the Nymphs, crossing the Sacred Way near the point where the road to Eleusis now leaves the Peiræus road, and so in a wide circle through the king's garden to the Ilissus and the Hill of the Muses again. A few years later the Peiræus was also fortified and connected with Athens by the famous "long walls," one of which now forms the roadbed of the Peiræus railroad. At the same time that these great building operations were being carried out the power of Athens was confirmed by the formation of the Delian Confederation, under Aristides, a confederation that made Athens the head of all the islands of the Ægean and brought her in the revenues necessary to her public undertakings.

But if Themistocles and Aristides made Athens the most powerful city of Greece, it was their successors, Cimon, son of Miltiades, and above all, Pericles, who made her the most beautiful. To Cimon we owe the plan for a new Temple of Athena to replace the old Temple of Peisistratus, which had only been hastily repaired after its destruction by the Persians. For this temple Cimon found the Acropolis too narrow and too uneven ; for the rock of the Acropolis was not originally flat, as it now appears to be, but sloped gradually down from a point east of the Parthenon, its appearance resembling the roof of a house more than anything else. For his new temple Cimon laid a deep foundation on the south slope of the rock, using the old Pelasgic wall, which had formed the fortification of the Acropolis in pre-Persian times, as a retaining wall, and strengthening it by the great wall which now forms the southern boundary of the Acropolis. The ground on all sides of the temple was levelled up with alternate layers of stone chips and earth, and especially with hundreds of statues and votive offerings which had been left in fragments by the Persians. It is to this fortunate chance that we owe almost the entire contents of the Acropolis Museum—the archaic sculpture and terra-cottas there collected are the relics of the Persian invasion, buried for centuries under the surface of the Acropolis, and only brought to light in the general excavation of 1885 and the succeeding years.

The plan of the Parthenon, then, was due to Cimon ; but it was carried out in its present form by Pericles, who, in one office or another, usually as general of the Athenians, exercised a commanding influence over the development of Athens for over thirty years (from about 429 to 460). Pericles apparently found the ground plan of the temple, as built by Cimon, too narrow, for he widened the original foundation by several feet, at the same time moving the axis of the building slightly to the north. This widening was probably due to the introduction of the plan for the gold and ivory statue which was to stand in the central hall. Of course, such a building required years for its completion. In fact, it was probably not entirely finished until about 434, although the formal dedication took place in 438, when Athena Parthenos was first exhibited to the people. No expense was spared to make the temple the finest offering to a patron goddess the world had ever seen. The entire building was of Pentelic marble, from the quarries which we can see even to-day on the slopes of Pentelicus. Not only were the pediments filled with groups of figures representing the birth of Athena from the head of Zeus and her contest with Poseidon for the land of Attica, but the metopes, which were usually left plain in Greek temples or only partly sculptured, were all filled with reliefs calculated to arose the enthusiasm of the Athenians, the battle of the Centaurs and Lapithæ, the capture of Troy, the contest of the Athenians and Amazons ; while around the cella wall ran the great frieze of the the Panathenaic procession, culminating over the door in the assembly of the gods and the ceremonies connected with the delivery of the sacred robe which was borne every four years by Athenian maidens and laid on the knees of the old statue of the goddess.

But the plan of Pericles did not stop at one temple. At the same time that the Parthenon was in course of construction, the little Temple of Athena Nike was built on the great bastion that formed the western end of Cimon's wall, and on the hill of Colonus Agoræus, overlooking the market-place, rose the Temple of Hephaestus, which we have come to know falsely as the Theseum. Other temples were built or remodelled in other parts of Attica, at Sunium and at Eleusis, the Acropolis was filled with a multitude of statues, dedicated both by private individuals and by the State; and finally, in the years between 432 and 437 was built the great Propylæa as a fitting entrance to the most glorious sanctuary of the Greek world.

It was probably during the period of Pericles's leadership that the other great building of the Acropolis, the Erechtheum, was planned and begun, although it was not finished until after 408. The cause of this was the war between Athens and Sparta, which, at first favourable to the Athenians, ended in the crushing defeat of Ægospotami in 404, the destruction of the long walls and the placing of a Spartan garrison on the Acropolis. To be sure, this foreign domination was soon overthrown. In the very next year, Thrasybulus, the second saviour of Athens, came over the passes of Parnes from Thebes, captured the border post of Phyle and drove out the Spartan garrison. The Athenian fleet regained its power, and in 393, after a series of successful campaigns in the Ægean, Conon was able to return in triumph to Athens and to rebuild the long walls. But the power of Athens was broken. The victories of Conon with the aid of Pharnabazus, a satrap of the great king, and of Evagoras, king of Cyprus, and his policy of relying on foreign aid, now became the leading principle of Athenian politics.

But if the fourth century is a time of political degradation, in the realms of the mind it is almost more distinguished than its predecessor. In this century Plato and Aristotle founded their schools—the Academy, on the banks of the Cephisus, the other in the Lyceum, on the slopes of Lycabettus, near the spot where the American school now stands. The age of the great tragedians was over, but the younger branch of comedy eceived its fullest development in the fourth century. In sculpture, although the age of Pheidias and Polycleitus is passed, the fourth century gives us Scopas and Praxiteles and Lysippus ; while in the field of oratory we have only to recall the great name of Demosthenes to be convinced of the mental attainments of the age of Alexander the Great.

Naturally, such a period of weakness in the State, although accompanied by great mental progress, was not favourable to large building operations. Most of the public monuments of this time are private undertakings, like the monument or Lysicrates and the monument of Thrasyllus, meant to commemorate private victories in musical and dramatic contests. Fine grave monuments also were in fashion, as one sees at the Street of the Tombs, outside the Dipylum, and in the collection in the National Museum. Yet, under Lycurgus, the Athenians found means to build their first permanent stadion and first gave their theatre and marble covering.

After the death of Alexander in 323 the politics of Athens sank to the lowest level ; any support from outside was gladly welcomed, and the latest benefactor was the most popular. It was the kings of Pergamum especially who adorned Athens at this period—Attalus I., with the groups of gods and giants, Amazons and Athenians, Greeks and Persians, Gauls and

Greeks, of which so many copies exist. Eumenes II. built the long stoa to the west of the theatre, and Attalus II. adorned the market with another even larger stoa.

With the capture of Corinth by the Romans in 146 the whole of Greece fell under the sway of Rome, and a new and, on the whole, happier era began for Athens, for the Romans loved and respected her as the home of their own higher culture, and their rule was never so severe in most of the provinces. To this period we owe many of the extant buildings—the Temple of Rome and Augustus, east of the Parthenon, the Tower of the Winds, built by Andronicus of Cyrhestes, the gate of the oil market near it, built by Augustus, and the pedestal of Agrippa, erected by the Athenians themselves. The last additions to her glories Athens received under the Emperor Hadrian, who finally completed the Temple of Zeus, almost seven hundred years after its inception under Peisistratus, and built his gate to divide the new quarter he had established from old Athens. The great gymnasium in the market is another of the buildings of Hadrian, while his contemporary, Herodes Atticus, who owned all the country about Marathon and Pentelicon, covered the stadion with marble, as his modern successor, M. Arcroff, has so lately proposed to do, and built the theatre which bears his name in honour of his wife Regilla.

Thus we have the completed picture of Athens as she stood in the days of her greatest splendour—the second century A.D. —the Acropolis crowded with statues and offerings and crowned by the Parthenon, her gods the apparent rulers of the civilised world, her streets crowded with the youth of every land, who gathered about her philosophers and scholars. And yet this was only the last flare of the fire before its extinction. Only a little more than a century after the death of Hadrian the Goths appeared before Athens, and were with difficulty repulsed; and in 395 the Ostrogoths, under Alaric, captured the city.

Another influence, too, was at work to destroy the prestige of Athens. About the middle of the first century, in 58 A.D., a Jew had appeared in Athens and proclaimed an "unknown god," and then he had gone away and no one had thought any more about him. Yet the seed he sowed had been working, and in 325 the Emperor of Rome declared himself a convert to the new faith of Christianity. In spite of all this the philosophers continued their teaching in Athens, and it was not until 529 that the Emperor Justinian formally closed the philosophic schools. The Parthenon was converted into a Christian church, at first of the Sacred Wisdom, then of the Holy Virgin.

In fact, the whole later history of Athens is summed up in the history of the Parthenon. In 1204, after the capture of Constantinople by the Venetians in the fourth crusade, Athens became subject to Frankish dukes, and the Parthenon church was transferred from the Eastern to the Western church. In 1456 Athens was captured by the Turks, and a few years later the Parthenon was changed into a Mohammedan mosque. Finally, in 1687, a Venetian army under Morosini, in an attempt to capture Athens, dropped a bomb through the roof of the building upon a lot of powder which the Turks had stored inside, and, after a life of over 2,000 years, the pride and glory of the age of Pericles was shattered into a thousand pieces. The siege was successful. The Turks evacuated the Acropolis, but Morosini was unable to hold his conquest, and in a few months Greece groaned again under the Turkish yoke—a yoke that was not lifted until the war of 1821 and the establishment of the Greek kingdom.

The subsequent events of the history of Greece are well known. In 1832 Otho of Bavaria became the first King of Greece, to be driven out, after a reign of thirty years, in 1862. In the next year William of Sonderburg-Glücksburg was elected king, and as George I. he has reigned ever since. The events of last spring are too recent to need repetition—the utter weakness and absolute worthlessness of the Government were only too plainly shown. But the weakness and worthlessness of the Greek people were not shown and cannot be shown. They are like all southern peoples, quick, impulsive and utterly unpractical. What they need is a strong foreign control by honest rulers, a government that will lay the greatest stress on internal improvement and education along practical lines—that will try, in fact, to rule the country according to nineteenth-century ideas, and will not rely on a reputation made over 2,000 years ago.

THE SOUTH KENSINGTON MUSEUM.

THE following is the text of the memorial addressed to the Prime Minister, to which we referred last week :—

Whereas in 1890 Parliament voted 100,000*l.* for the purchase of a site at South Kensington upon which to erect suitable buildings for the Science Museum of the Department of Science and Art and for the extension of its science schools, in accordance with the recommendations of the Royal Commission over which the Duke of Devonshire presided in 1874, as well as of various committees and other high scientific authorities and of a Treasury committee appointed in 1889;

And whereas when in 1891 the Government had proposed to erect an art gallery on the site, a memorial signed by the President and officers of the Royal Society and representatives of the Universities of Oxford, Cambridge and of many other learned bodies both in London and in the provinces, was addressed to your lordship, showing cause why the site should not thus be allocated;

And whereas the scheme was withdrawn, and it was stated by the late Right Hon. W. H. Smith, M.P., in the House of Commons on April 16, 1891, that the "Government has at disposal more than three acres of vacant land facing the Imperial Institute, and considerable areas beyond to the south of the present Southern Galleries. A portion of these vacant lands can be utilised for the extension of the College of Science and for the future growth of the science collections. Additions to the College of Science must, in any case, take the form of a separate building divided from the present building by Exhibition Road," while the Chancellor of the Exchequer, the Right Hon. G. J. Goschen, informed the deputation which waited on the Lord President of the Council in May 1891 that "We hope to bring science into one centre fronting the Imperial Institute;"

And whereas this arrangement which left the ground on the east of Exhibition Road for the extension of the Art Museum has been generally accepted since 1876, when the Royal Commission for the Exhibition of 1851 offered land and a building with a view of carrying out the recommendations of the Duke of Devonshire's Commission in 1874 to provide the needed accommodation for science at South Kensington;

And whereas we are informed that this arrangement is in danger of being altered by the erection of science buildings on the east side of Exhibition Road;

We, the undersigned members of the Royal Academy and others practising various branches of the arts as a profession, desire most respectfully to express to your lordship our strong opinion that it is desirable to adhere to the former policy, which has been acted upon and publicly acknowledged by the Government since 1890. Considering the urgent need of much additional space even for the present art collections of the South Kensington Museum and the necessity for making some provision for their proper development, we are convinced that any attempt to provide on the east side of Exhibition Road for the necessary expansion of the science buildings will render it impossible to meet the future requirements of the industrial arts, for the promotion of which the South Kensington Museum was founded. We also feel that in praying your lordship to reserve for art that portion of the land which still remains vacant on the east of Exhibition Road we are not making an exorbitant demand. The whole plot of ground belonging to the Government on that side is much smaller than that devoted to the Natural History Museum, which only represents one branch of science without either teaching or applications, while the space on the east of Exhibition Road has to provide not only for the Art Museum but also for the administrative offices of the Department of Science and Art, the Royal College of Art, and part of the Royal College of Science.

The memorial has been signed by the following ladies and gentlemen :—

Sir Edward J. Poynter, P.R.A., Sir W. B. Richmond, R.A., Frederick Goodall, R.A., G. W. H. Boughton, R.A., Walter W. Ouless, R.A., Ernest Crofts, R.A., Thomas G. Jackson, R.A., Hamo Thornycroft, R.A., H. H. Armstead, R.A., Harry Bates, A R.A., Alfred Gilbert, R.A., Briton Riviere, R.A., E. Onslow Ford, R.A., William Stott, of Oldham, John M. Jones, W. P. Frith, R.A., Frank Dicksee, R.A., Phil. R. Morris, A.R.A., George Frampton, A.R.A., Hugh de T. Glazebrook, Luke Fildes, R.A., Val Prinsep, R.A., Marcus Stone, R.A., Colin Hunter, A.R.A., G. F. Watts, R.A., John R. Clayton, Reginald Barratt, Frederick Smallfield, Lewis F. Day, Thomas J. Grylls, Morant & Co., L. Alma-Tadéma, R.A., Andrew C. Gow, R.A., Sydney P. Hall, Alfred East, John Charlton, Oliver Murray, A.R.A., C. E. Johnson, J. Y. Hunter, R. Phené Spiers, F.S.A., Gordon Thomson, Sir John Tenniel, Edmund M. Wimperis, Herbert Schmalz, S. Mileham, James E. Grace, Harold Rathbone, H. R. Hope-Pinker, H. Cecil Drane, G. E. Wade, Lionel Cust, Walter McLaren, Alfred Drury, Fanny W. Currey, W. Hounsom Byles, L. Fairfax Muckley, R. Falconer MacDonald, Elinor Halle, J. Fitz Marshall, R.B.A., May E. Gordon, A. T. Yowell, Mary Grace, Henry T. Wells, R.A., J. Callcott Horsley, R.A., retired, William F. Yeames, R.A., Seymour Lucas, R.A., elect, Eyre Crowe, A.R.A., G. D. Leslie, R.A., Thomas Brock, R.A., W. Holman Hunt, Sir Edward Burne-Jones, Arthur Severn, C. E. Hallé, Thomas Stirling Lee, Gleeson White, Walter Crane, Lord Carlisle and W. Q. Orchardson, R.A.

The First International Congress of Public Art, organised by L'Œuvre Nationale Belge, will be held at Brussels from September 24 to 28 next.

NOTES AND COMMENTS.

IT must be galling to any one who holds opinions about ecclesiastical art resembling those of Lord GRIMTHORPE to find that he has been an agent for the erection of images which are supposed to be the signs and tokens of lawlessness. Lord GRIMTHORPE, having got hold of a faculty, was able to gratify himself as an amateur builder with a transformation of the old abbey of St. Albans. But he could not make up his mind about the altar-screen. Empty niches were appeals for figures, and his lordship had not the courage to fill them with statuettes of his rivals of the Parliamentary Bar and the old Benchers of Lincoln's Inn. To remove what was left of the screen was more than he could screw himself up to do, for Lord GRIMTHORPE is not a complete vandal, although by his principles he should be merciless towards things which were supposed to be objects of idolatry. While he was hesitating through theology and archæology pulling his robe in opposite ways, Mr. H. H. GIBBS appeared. He asked for permission to introduce the statues which were required, and it was given by the holder of the faculty. The niches were filled very slowly, and after five years Mr. GIBBS proposed to introduce sculpture on a larger scale and of more importance in an ecclesiastical sense than the figures of saints, which were harmless, for few of the congregation could identify them. Lord GRIMTHORPE demurred, but Mr. GIBBS decided to seek a faculty of his own, and although there was a compromise necessary, he became independent of his lordship. Mr. GIBBS was afterwards raised to the peerage, and a few days ago he obtained another faculty. Lord GRIMTHORPE and Lord ALDENHAM can now claim to be the co restorers of St. Albans. According to Lord GRIMTHORPE, "anybody can see in a minute the absurdity of comparing the cost of restoring visibly ten times the area and twenty times the bulk of the parts done before Lord ALDENHAM began with what remained to be done." But however big may be the area and bulk they only lead up to the rival restoration which becomes the crown of the work, and Lord GRIMTHORPE must have a misgiving that all his expenditure will, in the eyes of posterity, be treated as no more than a means for producing area and bulk. This is to be regretted, for in common with most architects we have a weakness for Lord GRIMTHORPE. His airs of infallibility are always exhilarating. If he had followed the prudent jog-trot course and employed an architect there would be no hesitation at the crucial moment about the treatment of the screen, and Lord GRIMTHORPE'S name would be associated with St. ALBAN'S as long as the church endured, instead of his resembling one of the two kings of Brentford, who are indistinguishable.

IT is remarkable that JAMES WYLD'S great globe, which was erected in Leicester Square as one of the attractions of 1851, should not have inspired any geographer with a desire to erect a bigger and more perfect model of the terrestrial ball. Professor ELISÉE RECLUS had contemplated a work of the kind for Paris in 1900, but as politics have driven him from France, it is doubtful whether any man or a company will have the courage required for such an undertaking. A paper read by M. RECLUS at the meeting of the Royal Geographical Society on Monday suggests that the project was not inspired by financial considerations. He maintains that truthful representation of a fragment of a sphere is impossible on a plane surface; a sphere or fragment of a sphere must be reproduced by another sphere or fragment of a sphere. But spherography, although the most important department of geography, has not kept pace with cartography, in which immense progress has been made. Even scientific people are not yet sufficiently convinced of the absolute necessity of studying geography on images of our planet reduced to a given scale with the real proportions. If the scale of the globe were very small—one to ten or twenty millions, for example—the surface had to be kept exactly even, polished, so to say, because the proportional size of highlands and mountains could not be represented. In larger spheres another element of truth and beauty was added, in that the actual relief appeared on the curvature of the model. The system of exaggerating altitudes was utterly bad, contrary to real science, and to be discouraged by all geographers having respect for nature and her laws. But as soon as the sphere was large enough to show at least one-millionth part of the real proportions then the heights and depths as well as the planimetric dimensions should be represented on that scale. On a large globe on a scale of 1 : 100,000, rugosities of the surface might be finely shown, even hillocks 50 metres in height. Such representation of ordinary heights would afford an unexpected advantage by furnishing a standard of comparison, since those looking at a relief would easily estimate the real dimensions of a country by the sight of the ridges and mountains that diversified the surface. Professor RECLUS said the moment had come for a grander representation of the earth than had hitherto been made, for the erection of a model globe which would be as scientifically accurate as possible, and which, being kept continually under correction, would become not only a thing most beautiful to look at, but also a standard study for travellers and geographers. There is much sympathy for M. RECLUS in England, as elsewhere. His books suggest his competence to direct the construction of a model of the world as it is known. But the work should not be left to private enterprise. All civilised countries have an interest in the realisation of M. RECLUS'S project, and should bear a share in the expense. But where is the most fitting site for the great globe to be found? A piece of ground 500 feet long and 500 feet wide would be large enough, but the difficulty is to discover the city that would be universally admitted to be a sort of centre of the world to contain the model.

ONE of the most attractive parts of the Paris Exhibition of 1900, at least for architects and builders, should be the annexe which will contain models of some of the most important modern buildings of the city. They will be very costly representations. The model of the Hôtel de Ville is to cost 58,000 frs. As the model of the great church of the Sacré-Cœur on the top of the hill of Montmartre will not be in plaster but in cut stone, the expense will reach a larger sum. The New Sorbonne is also to appear, but the model will cost the comparatively small amount of 25,000 frs. The two palaces of the exhibition in the Champs-Elysées, and the Pont Alexandre III. will be among the structures to be reproduced on a small scale. Architectural models, which at one time were not uncommon, appear to be out of fashion, but if the collection which will be seen in Paris attains the success that is anticipated, we may expect to see a revival of an art with which SHAKESPEARE was better acquainted than with architectural representations on paper.

WAGNERITES and Ruskinites may not be aware that their idols were boarders in the same *pension* at Mornex, near Geneva. There was, however, a difference of eight years between the periods of their residence. In order that so interesting a circumstance may not be overlooked, a tablet of black marble has been placed on the wall of the pavillon they occupied, at the cost of Professor HENRI KLING and MM. ROBERT and LAWRENCE HARVEY. It bears the following inscription:—"Ici vécurent deux Immortels—RICHARD WAGNER, 1856; JOHN RUSKIN, 1863-64." WAGNER was implicated in the political movements of 1848, and after wandering from place to place found, like many other great men, a refuge in Switzerland. It was at Mornex he composed *Siegfried*, and sketched the libretto of *Tristan und Isolde*. Mr. RUSKIN'S admiration for Geneva and the country around is well known. The city he describes as "the centre of religious and social thought and of physical beauty to all living Europe, the most lovely spot and the most notable without any possible dispute of the European universe." Geneva is associated with many other celebrities to whom it gave hospitality and protection, and the example which MM. KLING and the Brothers HARVEY have set is deserving of repeated imitation.

THE WESTMINSTER ACCIDENT.

AT the Central Criminal Court, before Mr. Justice Grantham, on June 23, Mr. Charles James Chirney Pawley was indicted for and charged on the coroner's inquisition with the manslaughter of seven persons.

Mr. C. F. Gill appeared for the prosecution and Mr. Horace Avory and Mr. Hugo Marshall for the defence.

Mr. C. F. Gill: My Lord, in this case I am instructed by the Director of Public Prosecutions to take charge of this prosecution, and having had an opportunity of reading and considering the case as disclosed by the coroner's depositions, and having had an opportunity of forming an opinion on the material on which the conclusion was arrived at by the coroner's jury, and also the form of the verdict of the coroner's jury, it does not appear to me, subject to your lordship's view, that there is such evidence of gross culpable negligence as would entitle me to ask the jury to find a verdict of manslaughter. The case arises in consequence of the collapse of the interior of the portion of a block of unfinished buildings called Abbey Mansions, Orchard Street, Westminster, the property of Mr. Pawley.

Mr. Justice Grantham: I have not had an opportunity of seeing the finding of the coroner's jury, and I wanted to see on what it was founded.

Mr. C. F. Gill: The finding of the coroner's jury was as follows:—"The deceased met their deaths through injuries received by the collapse of a portion of the south block of Abbey Mansions. The cause of the collapse was owing to the faulty design and construction of the pier due to the culpable negligence of the architect. The jury are of opinion that some of the concrete in the roof was carelessly mixed and irregular in quality, but it was not the initial cause of the collapse. In the opinion of the jury a greater amount of public control should be exercised over the construction of buildings."

Mr. Justice Grantham: What is that about the concrete in the roof?

Mr. C. F. Gill: That is part of the finding, my lord.

Mr. Horace Avory: I have a shorthand note of it here.

Mr. Justice Grantham: No, there is nothing here on the Coroner's depositions as to that. I see there are several men who have been killed, it may be I may find one to which it is added. It is certainly most remarkable. I will go through them all. No, each of these seven is limited to the pier.

Mr. Gill: It is clearly wrong that should be so.

Mr. Avory: The finding of the coroner's jury was a special finding, and the passage with regard to the concrete in the roof should have been recorded.

Mr. Gill: It is clearly wrong; it was a written special verdict. The verdict ought to have been returned in the form in which it was handed in by the jury. There is no doubt that it was a verdict returned in the terms I have read to your lordship. One question in the case was the state of the concrete in the roof. A considerable amount of evidence was given as to the concrete, and the jury expressed the opinion that some concrete in the roof was carelessly mixed and irregular in quality, but it was not the initial cause of the collapse.

Mr. Avory: I was there, and I have a shorthand note of what took place. A long discussion ensued between us as to what the effect of the verdict was. The coroner said he should construe it as a verdict of manslaughter.

Mr. Justice Grantham: I do not think it is material now or that it is worth while discussing it further.

Mr. Gill: I was under the impression that it was before your lordship.

Mr. Justice Grantham: No it is not. I think the verdict ignores altogether the matter of the concrete.

Mr Gill: It is fortunate that there is a reliable report of the finding. Mr. Avory was present at the inquest, and contended that the finding of the coroner's jury should not be construed into a verdict of manslaughter. I am not concerned to discuss how matters are conducted before the coroners' courts; sometimes extraordinary things occur there. The result of the collapsing of the roof was that the floors gave way, and the unfortunate men met their death. At the inquest there was very properly a full and exhaustive inquiry as to what brought about this terrible accident. A great mass of evidence was given in order to deal with what the actual cause was. It turned a good deal upon the opinion of experts as to the weight a pillar might bear. There were considerable differences of opinion among the witnesses who were called, and there was a considerable body of evidence given showing the condition of the concrete in the roof. In the course of that inquiry before the coroner there was no opportunity of counsel addressing the jury or dealing with questions that have arisen in order to point out questions which might arise. The view I take is that there is no kind of evidence here to justify me in asking the jury to find the defendant guilty of manslaughter, and therefore it is unnecessary to embark on a long inquiry of this kind at the end of which I should not be acting rightly in asking them o find a verdict of guilty, and so I propose to offer no evidence.

Mr. Horace Avory: May I say a word on behalf of Mr. Pawley? As my learned friend has properly said, neither counsel nor solicitor representing an accused person before a coroner has any right to address the coroner or the coroner's jury upon the law or upon the facts. And I wish to call your lordship's attention to this fact, that the inquest was started under the impression—an impression created by a letter written by a witness named Collins—that this pier which was the subject of discussion had been constructed in a most negligent, and culpably negligent, manner, with soft bricks and mortar, and everyone was prepared to admit that if this had been its real construction it was most gross carelessness, and he would be guilty of manslaughter. Then Mr. Collins wrote a letter to a member of the London County Council—that was really before the inquest was opened—and it was referred by the London County Council to the coroner. This letter was read or stated to the jury before the inquest commenced, and they started upon this inquiry with the preconceived opinion that the pier had been constructed in this manner, and when I arrived on the scene it was clear to me that there was a notion prevalent in the court that this was the actual nature of the pier, the construction of which had been conducted in the most negligent way. When Collins gave evidence he repeated some of these statements, and swore that the pier was constructed with soft bricks and mortar, and that the joints of the iron girders were not bolted but merely tied with string. That was the evidence that this man gave on oath. I very soon after that had an opportunity of extracting from other witnesses who actually constructed the pier and others who saw it after it had fallen what the material was, and there was not a word of truth in his statement that it was constructed with soft bricks, but of good hard bricks and cement as every expert admitted. When I started on this inquiry the jury and the coroner looked with horror when I said that Collins had committed perjury and it was clear that he had committed perjury. That shows the way the inquiry was started, and there was a preconceived idea as to the way in which the pier was constructed. It was quite obvious that the jury were acting under the impression that because Mr. Pawley had not disposed of it——

Mr. Justice Grantham: Having an opportunity of giving evidence, and not giving evidence, he must be guilty.

Mr. Avory: Yes. That appeared to me to be the view which prevailed at the inquest. As you see by the depositions, it very soon became evident that the only issue in the case which the jury had to decide was whether the collapse was due to the centring of the concrete roof being struck too soon or whether it was due to the inherent weakness of the pier which supported the girders. That was the real issue upon which the case had to be fought. It was admitted by those who were responsible for striking the centring that some of the roof had only been laid about six days and a small part of it only four days, and the major portion of it not more than thirteen or fourteen days. It was admitted by those who were responsible for the laying of the roof, and it was admitted by the expert who was called and upon whose evidence this verdict was found, that seven days was the minimum safe time to strike a concrete roof of this description, and therefore some of it had been found to be struck within the safe time of doing it. Some of the witnesses on the other side said that twenty-one days was the only safe time in which the centring for a roof of such a thickness should be struck. Further, in their opinion none of the roof was sufficiently set to justify the centring being removed. It was also admitted by those responsible for removing it that Mr. Pawley himself had given instructions on the very morning of the accident that the centring was not to be removed because it was in his opinion not sufficiently set.

Mr. Justice Grantham: Have you got a copy of the plan showing the way in which the roof was constructed? I have no notion of how it was made up.

Mr. Avory: I can describe it in one minute; it was a flat roof, the girders go across.

Mr. Justice Grantham: Whether it was arched or not?

Mr. Avory: No, it was absolutely flat. The boards are bolted through and the concrete is simply poured in. The moment you remove the support underneath the thing may fall. Mr. Pawley himself had given directions that it should not be struck, but either by some accident, some misunderstanding, or something worse, the persons who were responsible for having laid this roof, in fact in the middle of that day, proceeded to remove the whole of the centring. There were independent contractors for the construction of the roof. While the men were actually engaged in the operation of removing the centring of the roof it fell, and the very first thing that would have been heard was the cracking of the roof, and actually on hearing the cracking they escaped with their lives in their hands to the parapet of the wall, and it could not be disputed that this collapse took place at the very time that the men were removing the centring from the roof. Therefore, if I had had an opportunity of addressing the jury or the coroner I

should have pointed out that the very way in which the men were removing the centring was the obvious cause of the collapse. My lord, on the other hand, in order to support this theory that it was the fault of the pier and that the pier gave way and so let down the roof, one witness was called as an expert for the purpose of establishing that. The district surveyor admitted that it never occurred to him that there was any danger or that there was anything improper about it. He said that his first view was that it was undoubtedly the concrete which fell from the roof that so caused the collapse, though he subsequently altered that opinion. He came to the conclusion that it was the concrete at the outset. There were three independent gentlemen all well known, including the Vice-President of the Institute of British Architects, and they all said that in their judgment they were quite satisfied there was nothing faulty in the construction of the pier and that the collapse was entirely caused by the centring being removed from the roof. On the other hand, the superintending architect to the London County Council, Mr. Blashill, was called, and he said he had formed an opinion that it was the pier which gave way. If his conclusion is right, then the very worst that can be said against Mr. Pawley is that he differs in opinion. The witnesses called on behalf of Mr. Pawley say that 7 tons per foot super were the safe load for such a pier. Mr. Blashill says that 5 tons per foot super are the safe load. In fact this pier had 6·9 tons per foot super on it. He went on to say that some architects went beyond 5 tons, some had gone as far as 7 tons, and he (Mr. Blashill) was not prepared to say that 7 tons per foot super was not a safe load. Mr. Gruning, the vice-president of the Institute of British Architects, said that 7 tons per foot super was perfectly safe for a pier of this construction, so, as the evidence stood before the jury, Mr. Pawley was not in fault, and there was even no evidence before the jury that there had been an error of judgment on his part. If that was so with regard to professional men, most of us here might be guilty of misdemeanour on account of errors of judgment. I make these observations only for the purpose of showing your lordship that in my view the very worst that could be put against Mr. Pawley was an error of judgment. Upon these depositions I say that no jury should have come to this conclusion. Other architects are prepared to say that 7 tons is a safe load for this pier. There were only 6 tons and a little over in this case at the time, and the district surveyor, in fact, has admitted since that his report saying that the accident had been caused by the faulty construction was possibly influenced by the opinion of his chief, the Superintendent Architect of the London County Council. He did say he had modified his view and that perhaps it might be the concrete that fell. For these reasons, if I had not anticipated that this course of offering no evidence would be taken by the Treasury, I should undoubtedly have moved in the High Court to quash the inquisition by *certiorari*, because there were many grounds open upon which I could have moved for it to be quashed.

Mr. Justice Grantham: How far up did the pier go—right to the top?

Mr. Avory: Yes, my lord.

Mr. Justice Grantham: Gentlemen, this is a very important question which has been discussed by the learned counsel, because a course has been taken which perhaps will disappoint some people very much. It is quite right that this course should have been taken openly, so that everyone may understand what has happened. It was a very lamentable accident, a large building suddenly falling and sending seven men into eternity at once and injuring others. Naturally people said somebody must be to blame, and undoubtedly, unless it was a pure accident, somebody ought to be punished, and naturally they searched about to see who was to blame, and the first thing that was suggested was who was the architect? That is the view taken by the majority of the public generally at any rate. Unfortunately it does seem to have been initiated by a letter written by one of the witnesses, who for some reason or other was apparently so interested in some way, at any rate he seems to have made a statement in his letter which was not justified by his facts, and undoubtedly that letter seems to have influenced the minds of the jury and also the mind of the coroner. It was a very difficult matter to investigate, and I have no fault to find with the way in which the inquest was held. After a very long inquiry and a mass of evidence which took me five hours to read, the coroner came to the conclusion on the finding of the jury that the defendant was solely responsible for this accident, and that the negligence was culpable, and that therefore a verdict of manslaughter had been found by his jury. It was certainly unfortunate that the whole verdict was not put upon the coroner's depositions. I am not blaming any of the officers that I had not before me the exact finding of the jury. The Treasury very properly were desirous of knowing what view I took of this case, and I was requested specially to go through the evidence to tell them and advise them whether in my opinion they would be justified in occupying your time for at least a week, when at the end of that time it would have been impossible to say that he was guilty. I must say, therefore, from what I read, for the jury to have found a verdict of manslaughter against the defendant I think was a very extraordinary finding and quite wrong. I had no hesitation in advising the Treasury that they would not be justified in asking the jury to find the defendant guilty of manslaughter. In my judgment the primary cause of the accident was clearly the removing of the centring from the concrete. Not being an architect, and not knowing at first what that centring meant, in going through the evidence I endeavoured to find whether the exact construction of the roof was described, but failed to find any such description, and that was why I asked whether the roof was arched or not. The conclusion I came to was—if I had to come to any conclusion as to what was the cause of the accident—that it was certainly the removal of this centring; and the accident happened immediately upon its removal. It is a very remarkable thing that the accident happened simultaneously with the removing of the centring. While the centring, unfortunately, is being so removed a crash or a rumble or something is heard and down it goes on to the girder below. That fell on to the girder on the next floor below, and as that fell the weight of the falling mass would be increased, and as it fell to the next floor below the weight would be greater by the weight of that floor and so it goes right the way down with increasing weight, but it must all have happened so simultaneously that it was difficult to know which had fallen first. You cannot imagine how short a time the whole thing falling on the iron girder would occupy; it would only be a few seconds. Therefore I am not at all surprised that the jury found it difficult to say which fell first. You must look at the case as well as the evidence on which it is based. The allegation against Mr. Pawley was that there was a faulty construction of the pier in two ways, that soft bricks instead of hard bricks were used and mortar instead of cement. It appeared that someone had sold 100,000 bad bricks for this work, and the statement was that they were found to be bad and were ground up for mortar, but no doubt some of them had been used for building, and the suggestion was that they had been used in this pier. If they had been, of course, and the pier had to take the weight of something like five or seven tons per foot super, it would have made the man guilty of culpable negligence. It is also said that mortar had been used instead of cement. That, of course, would influence the jury. It is rather difficult for me to know the course the evidence took. The evidence of each witness is all put together, and a great many other witnesses were called in the interval before a particular witness was recalled, and so the matter went on, and it is almost impossible for me to follow the various statements. I come to the conclusion, after having gone through the whole of the evidence, that there was no evidence to justify the statement that in the construction of the pier soft bricks and mortar had been used. I find there was nothing to justify the statement except Collins's statement. In my opinion that is a false statement, but whether intentional or not I do not say. I come to the conclusion that it was a false statement of fact and that the pier was not made of soft bricks, but of proper hard bricks and cement, and that when it was examined it was found to be of good solid construction. That being so, and there being no evidence whatsoever that the cause of the accident was the collapse of the pier, and the accident being through no fault of the accused, and the fact being that this concrete does require a considerable time to set, and that you ought to take the extreme view with regard to the period of setting instead of the shortest time; and, again, there being a doubt as to the composition of the concrete, and whether a certain class of material had been used and required a lengthy period to dry, on these questions I came to the view that the real cause of the accident was the removing of the centring from the concrete, and at any rate so far as this trial was concerned it would be most unfair to ask any one to find the prisoner guilty where some one else, if any one, was guilty, and consequently the whole time would have been wasted by holding the inquiry over again, and therefore I advised the Treasury, perhaps I should not say that, but I did suggest this course should be adopted. The whole matter has been thoroughly investigated, and you will say therefore that the prisoner is not guilty.

The Clerk of the Court: You say, gentlemen, the prisoner is not guilty?

The Foreman: Not guilty.

Sir Arthur Arnold has given notice of the following motion to be proposed at a meeting of the London County Council:—"That it be an instruction to the general purposes committee to make inquiry in Paris, Berlin and Brussels as to the connection which obtains in those cities between the operatic and dramatic stage and the State and the municipal governments respectively, and to report to the Council thereon."

ESHER AND CLAREMONT.*

CLAREMONT has attained to its highest importance among the demesnes of Surrey since the time of Queen Anne. In her reign, Sir John Vanbrugh, the architect, purchased some land at Esher and erected on it a small brick house for his own residence. This dwelling, which stood on low ground, without any advantage of prospect, was subsequently sold to Thomas Pelham Holles, Earl of Clare, afterwards Duke of Newcastle. He added a magnificent room for the entertainment of large companies when he was in administration, and greatly augmented the estate. He likewise caused a castellated prospect-house to be erected on a mount in the park, calling it after his own title, Claremont, which subsequently became the general name of the estate. During his occupancy the grounds were laid out under the direction of Kent, whose talent as a landscape gardener has been proved at Esher Place. On a tablet in Claremont is the following :—

"Sir John Vanbrugh, Knight, owner of the estate, 1708, a dramatist and artist of celebrity. He built the first mansion of which the gardens were laid out under Kent, by orders of Holles, Earl of Clare and Duke of Newcastle, Prime Minister to George II. and III., and bestowed on it the name of Claremont."

On the decease of the Duke of Newcastle in 1768, *sine prole*, the title became extinct, his brother, the Right Hon. Henry Pelham of Esher Place, having died without male issue in 1754. This property was afterwards sold by the Duchess of Newcastle to the gallant Lord Clive, to whose vast talents and indefatigable exertions, both in civil and military capacity, the foundation of British power in India must unquestionably be ascribed. Whilst Claremont remained in his possession the grounds were remodelled, and a new mansion was built under the direction of Lancelot Brown, on whom the sobriquet of "Capability" Brown was bestowed by his contemporaries, in consequence of his frequent use of that word when giving advice in his twofold profession of landscape gardener and architect. Manning states that Brown was employed to execute the work "without any limitation of expense," and that he "performed the task much to the satisfaction of his lordship, who did not regard the cost, which is stated to be more than 100,000*l*."

While in a paroxysm of acute pain, Lord Clive, by reason of the ignominious charges insinuated against him during his government in India, committed suicide at his house in Berkeley Square, 1774.

At that time, Edward, his eldest son, afterwards Earl of Powis, was in his minority, and Claremont was subsequently disposed of to Viscount Galway. The next possessor was the Earl of Tyrconnell, who in 1807 resold the property to Charles Rose Ellis, who in 1816 conveyed the whole to the Commissioners of His Majesty's Woods and Forests, under the Act (26 George III. cap. 25) for providing a suitable residence for H.R.H. Princess Charlotte (the only daughter of the Prince Regent, afterwards George IV.) upon her marriage with Leopold, Prince of Saxe-Coburg.

It was at Claremont that for a short yet blissful period this amiable princess lived in all the happiness of conjugal and domestic union, and here she drew her last breath in childbed on November 6, 1817, having been delivered of a still-born infant a few hours previously. Never before had the ruthless destroyer of men struck a being whose loss was so deeply mourned—so universally lamented. Whilst the bereaved prince continued to reside here, and for a considerable time afterwards, the apartment in which the princess died was kept closed and its furniture undisturbed. From the time, however, of his leaving this country to take the throne of Belgium the house has been occupied, and it was one of the favourite residences of the Queen when Princess Victoria. Louis Philippe and Marie Amelie, king and queen of the French, resided at Claremont from 1846 to 1866, when His Majesty King Leopold died.

Claremont is said to be "the only complete mansion that Brown ever built, though he altered many." It occupies a commanding eminence near the middle of the park, and forms an oblong square; the building is of brick, but the windows and dressings are of stone. On the eastern front is a stately portico of the Corinthian order, within the pediment of which is a large sculpture of the arms of Lord Clive. The saloon, or entrance-hall, approached by a flight of twenty-one steps, is ornamented by marble columns, and the walls are enriched by panels of various devices in low relief. Besides the hall, which is of an oval form, and the great staircase there are eight spacious rooms *en suite* on this floor.

The library opens to the dining-room, in which is an excellent oil-painting of Queen Victoria by Winterhalter. The gallery is a capacious apartment, intended to have been fitted up with damask expressly chosen for it by the late Princess. It contains, however, a Persian carpet, sent by Lord Clive for this room, about 100 years old. Here are full-length portraits, both of the Princess Charlotte and Prince Leopold, by Dawe.

Claremont consists of about 300 acres, comprising park, pleasure-grounds and avenues. These are intersected by many good specimens of ornamental and hardwood trees.

At a short distance from the mansion, on the west, is the mount which gives names to the estate, and which rises with a rapid sweep to a considerable height. It is surmounted by the castellated tower (called the Observatory) built, as already stated, by his Grace of Newcastle, and which commands from its summit most extensive and beautiful prospects over the circumjacent country. It is constructed with brick in three storeys, with stone dressings.

About a quarter of a mile from the house in a north-westerly direction is the mausoleum of the late Princess Charlotte. It is in the Pointed style of architecture. This structure was originally designed by the Princess for an alcove or open seat. Being unfinished at the time of her decease, it was completed by Prince Leopold in a more expensive manner than was at first intended, and converted into a mausoleum to her memory. It stands on a commanding plot of ground artificially heightened; in front there is a garden, whence a bird's-eye view is obtained over the lake below and its surrounding foliage. The interior has a groined ceiling enriched with tracery, over which a chastened mellow light is shed by the stained-glass that ornaments the windows.

In descending from the garden towards the lake a finely varied succession of lawns and shrubberies, interspersed with occasional forest trees of stately growth, delights the eye and leads to a spacious expanse of water surrounded by trees. This lake occupies about five acres. On the north is a luxuriant bank of rhododendrons and other evergreens; in the centre is a finely-wooded islet, and on the south-west side, backed by large trees and underwood, is some artificial rock-work connected with a ruined grotto.

In the farm grounds on the eastern side of the park is an obelisk erected by the Duke of Newcastle during his residence here; it is surmounted by the Pelham crest—a peacock.

At a short distance from the house, on the north-east side, are the flower and kitchen gardens, which with the slips include about ten acres of ground; of these nearly seven acres are enclosed by strongly-built walls of red brick, the erection of which is ascribed to Sir John Vanbrugh, whose own house stood on the low ground between the two cedar trees directly in front of the present mansion.

Claremont Park is about three and a half miles in circumference, the chief entrance being in Esher, on the road to Leatherhead. It is surrounded by a ring fence, and includes about 300 acres; but the whole extent of the Claremont demesne is probably not less than 1,610 acres, its late royal possessor having greatly enlarged the estate by the purchase of adjoining lands.

Claremont became the residence of H.R.H. Prince Leopold, Duke of Albany, who brought here his bride, H.R.H. Helen, Duchess of Albany, Princess of Waldeck and Pyrmont, on April 27, 1882. Her Royal Highness, with her children, the Princess Alice of Albany and the young Duke of Albany, continues to reside here.

Leaving Claremont, a pleasant walk through the pine woods brings us to Waterville, a portion of the ancient Manor of Esher-Waterville. It is mentioned in Domesday Book as 5 hides of land in Esher, pertaining to the Manor of Cobham belonging to the Abbot of Chertsey, and was held of the abbot by William de Waterville. From that time down to the present the Manor has passed through various hands, and been broken up into various parts, the principal portion being owned by the Commissioners of H.M. Woods and Forests. The portion after we leave the bridge belongs to Mrs. Frewen, of Arbrook.

We have now returned to Esher, about which beautiful village much has been said and written. William and Mary Howitt made it their home for many years, and roamed amongst its pleasant woods and lanes, and before their day the poet Edward Moore, who wrote between 1712 and 1757. In a poem entitled "Virtue in Search of an Earthly Abode," he sings :—

Long thro' the sky's wide pathless way
The muse observed the wand'rer stray
And marked her last retreat.
O'er Surrey's barren heaths she flew,
Descending like the silent dew,
On Esher's peaceful seat;
There she beholds the gentle Mole,
His pensive waters calmly roll
Amidst Elysian grounds;
There thro' the wanderings of the Grove
She leads her family of love,
And strews her sweets abroad.

Descending from poetry to the baldest prose I shall now give you some account of Esher, and I find from the local directory that it is a parish on the Portsmouth road, four miles

* A paper read by Mr. Charles Findlay at the visit of the members of the Upper Norwood Athenæum.

south-west from Kingston and fifteen miles from London. There were several manors or parts of manors in Esher (Aissela) at the time of Domesday Survey, the principal one belonging to Leutfields Cross Abbey. In the reign of Henry III. the abbot sold it to the Bishop of Winchester, and it remained in the possession of that See until the reign of Henry VIII., when it formed a part of Hampton Court Chase. Queen Mary reconveyed it to the Bishop of Winchester. Queen Elizabeth bought it and conveyed it to the Earl of Effingham, who sold it to Sir Francis Drake. Lord Clive bought it in 1768 and built Claremont Palace. Esher is described in Cromwell's "Commission of Enquiry" as "distant from Thames Ditton about a mile and a half, the way indifferently good both summer and winter." The incumbent was Mr. John Bunting; his church was called Esher or Sandy Chapel, worth about 50*l.* per annum. That was about the year 1658. As far back as 1284 we find that the rectory was conveyed by the Prior of St. Swithin to the Bishop of Winchester, and the conveyance was confirmed by King Edward I. in that year. Of the old parish church or Sandy Chapel very little history can be found. St. George's Church, the present old church, consists of a nave only with chancel, and the Duke of Newcastle built a chamber pew. The chancel windows are said to have been famous for stained-glass. There are several interesting monuments in the old church. Against the south wall is a marble monument by Flaxman. On the top is a dove and on the tablet the words, "The Lord giveth and the Lord taketh away." Below is carved a bunch of lilies. This was erected in memory of the wife of Charles Rose Ellis, the only daughter of Lord Hervey, and who died at Nice in January 1803. Various other tablets are to be seen, but I shall not weary you by describing them. In the chamber pew built by the Duke of Newcastle the Queen used to attend the services in St. George's Church.

In 1852 the old church was found to be glaringly deficient in accommodation for the needs of the residents, and the then rector says in a circular issued to the parishioners, that "there is no possibility of extending the church inasmuch as it was surrounded to its very walls by graves and family vaults." The new church was accordingly built, and was consecrated by the Bishop of Winchester, under the name of Christ Church, on May 4, 1854. From the Registry of the Commissary Court of Surrey, Doctors' Commons, it is learned that Her Majesty's Commission, in exercise and execution of the power of authority vested in them, with the consent of the Bishop of Winchester, of the patron and the rector, declared that the said new church called Christ Church "shall be and the same is hereby substituted for the old parish church of St. George in the said parish of Esher, and they transfer all the rights, endowments and emoluments belonging to the old parish church of St. George at Esher to the rector or incumbent thereof and his successors for ever." This document was signed and sealed by Her Majesty's Commissioners, the Bishop of Winchester, the patron and the rector, on May 9, 1854. The reredos was erected by Mr. Few, one of the parishioners, in memory of his wife, who was buried in the churchyard on April 17, 1878.

The monument in the church in memory of H.R.H. Leopold, Duke of Albany, was unveiled on December 3, 1884, by the Duchess of Albany.

There are many beautiful and interesting monuments in the new churchyard. Among others, one to the memory of Rev. Charles Clarke, who was the author of several works of fiction and an eminent contributor to "Baily's Magazine, and besides, he carried on the famous school in the "Old House." What the school was famous for I do not know, but some of you may. He was buried on July 27, 1870.

Samuel Warren was buried near. He was, as all of you know, the author of "Ten Thousand a Year," "Now and Then," "The Lily and the Bee," &c.

The monument erected by Lord Esher over the vault which was built on the occasion of the death of Lord Esher's second son, Eugene Leopold Selwyn, of the Scots Guards, is a fine structure, and is remarkable in that it represents the two life-size figures of Lord and Lady Esher, who are still alive.

Leaving the church, we now come to Mr. Williamson's studio, and I am sure one and all of us are highly indebted to Mr. Williamson for affording us the opportunity of witnessing so many beautiful works of art as are displayed here, and of being admitted, as it were, into the very arcanum of the sculptor's art. So many excellent examples of Mr. Williamson's genius were before our eyes, all equally fine, that it is difficult to particularise or set out one before another. But I think you will all agree with me that in nothing does Mr. Williamson so much excel as in his fine depicture of the ideal. His faces are exquisite, and not copies from Greek or Roman gods or heroes, but the outcome of his own genius. Charles Kingsley's "Hypatia" strikes us at once on entering the studio. It is a magnificent figure, and shows out grandly the genius of the sculptor. The statue of Liberty is also a striking one. In both of these the type of female beauty, as conceived by Mr. Williamson, is finely exemplified. Words fail me to describe all we saw, but you have the recollections of it in your own mind. The studio teems with busts and statues of the Royal Family from Her Majesty down to the little York princes, which shows the high esteem in which Mr. Williamson is held by Her Majesty and her illustrious house.

I must apologise for having kept you so long. The difficulty is that one cannot well condense historical dates and facts when these are in sequence, and I had little time at my disposal for getting up this paper. As it is, I have had to leave out much that would have interested you, and other places worthy of a ramble have presented themselves to which I hope I may have the pleasure of conducting you at some future time—Esher Place, the residence of Sir Edgar Vincent, for instance. The grounds there are most extensive and beautiful, and the Place is of much historical interest, having been the residence of Cardinal Wolsey when he was ordered by Henry VIII. from Hampton Court.

ENGLISH ART IN THE EIGHTEENTH CENTURY.

IN the second of his course of lectures upon this subject, Mr. Humphry Ward dealt with the life and works of Sir Joshua Reynolds. He remarked that the great debt which English art and civilisation owed to Sir Joshua was not only due to his qualities as a painter, it was due in an almost equal degree to his personality. Perhaps his greatest achievement of all was to persuade the Court, the aristocracy and the men of letters that art is an essential part of civilisation. In two ways he showed that he was something more than a great painter. He was able to form general views about art and to state them authoritatively and in admirable literary form; and, moreover, his strong personal charm gave him the power of becoming and remaining the friend of the most influential people of his time. Proceeding to sketch the life of Sir Joshua, the lecturer described his early years, his residence in Italy from 1749-52, his immediate and wonderful success in London, and the different stages of his subsequent career, with the gradual modifications of his style. By a series of lantern slides he illustrated the wide scope of the painter's invention, and showed how, though he painted over 2,000 portraits, he seldom repeated himself, verifying Dr. Johnson's remark, "I know no man who has passed through life with more observation than Mr. Reynolds." Then, passing to the Discourses, he spoke of Sir Joshua's views on "the grand style," and of that curious paradox, noted by Mr. Ruskin, that his own immortal successes belonged to a class of art which he himself thought secondary, while his failures belonged to the class which he considered the highest. He told the story of the once famous picture of "The Infant Hercules," which was sold to the Empress Catherine for the then enormous sum of 1,500 guineas, and which a few years ago was found after a long search by an enterprising English lady, without its frame, with its face to the wall, hidden in the midst of a stack of pictures in one of the garrets of the Hermitage Palace at St. Petersburg. The contrast between the fate of these "grand style" pictures of Sir Joshua and his portraits, of which the value is rising every year, was curiously significant. The lecturer announced that the remainder of the course would be deferred till the autumn.

SCIENCE AND ART MUSEUMS.

THE select committee appointed to inquire into the administration and cost of the museums of the Science and Art Department met on Friday last to consider the terms of their report. Two drafts were submitted, says the writer of "Political Notes" in the *Times*, one by the chairman (Sir Francis Powell), the other by Lord Balcarres. After a brief discussion it was agreed that the chairman's report should be taken as a basis for discussion—or, to employ Parliamentary phraseology, should be "read a second time par. by par."—it being understood that certain of the recommendations formulated by Lord Balcarres should be added to Sir Francis Powell's document as amendments. Coming to details, the committee adopted, with some verbal modifications, the introductory paragraphs relating the circumstances in which the South Kensington and Bethnal Green Museums, the Museum of Practical Geology, Jermyn Street, and the Edinburgh and Dublin Science and Art Museums were formed, and the methods of administration which prevail in connection with these institutions; after which the proceedings were adjourned until Friday next, when the discussion of the recommendations which Sir Francis Powell invites the committee to sanction will be entered upon.

Sir Francis Powell's principal suggestions are that there should be an Education Minister of Cabinet rank having a seat in the Legislature, aided by a Parliamentary Secretary; that the Secretary for the Science and Art Department, like the Secretary of the Education Department, should have an office at Whitehall; that there should be advisers or visitors who

would assist the Department by suggestions or information in matters affecting the museums, but would not lessen the responsibility to Parliament of the Parliamentary chiefs; that, with a view to facilitating communications between the Parliamentary heads and the principal officers of the museum, one at least of the former should visit the museum weekly, or more frequently, and confer with such members of the staff as the state of current business renders it desirable that he should consult on the management of the museum; that, while leaving with the Parliamentary heads a wide discretion as to the duties of the staff, larger discretion as to purchases should be vested in the directors of the Science and Art Museums, and officers should be, as far as practicable, assigned to different divisions in the Art Museum in order that they may become experts; that the director of the Science Museum should possess scientific attainments, and that the director of the Art Museum should have like qualifications as regards art; that the staff at the South Kensington Museum should be increased; that, having regard to the annually increasing demand made by local museums and schools of art on the South Kensington collection for circulation, the Parliamentary grant for purchases should be increased; that admission to all the museums should always be free; that provision for science instruction and for loans for scientific objects be placed on the west side of Exhibition Road exclusively, the Art Museum, the Art Library, provision for art teaching and for loans of art objects being placed on the east side exclusively; that the Jermyn Street collection be removed to the west side of Exhibition Road, care being taken to preserve its special characteristics, save that the artistic pottery should be placed in the Art Museum; that provision be made for the residence of the principal officials in the immediate neighbourhood of the museums in which they are employed; and that negotiations be carried forward with a view to transferring to some local authority the site and structure of the Bethnal Green Museum, the Dixon collection of pictures and any other objects specially dedicated by donors under their wills or otherwise.

The alternative report prepared by Lord Balcarres recommends, *inter alia*, that the responsibility of administration should be localised; that the position of high officials should be clearly defined and that officials should not be "shuffled" from branch to branch; that papers in special subjects should be added to examinations and that the system of probationary reports should be immediately re-established; that the military garrison should be removed, the works department reorganised, large economies effected and the estimates thoroughly overhauled; that art referees should be discontinued and the rubbish in the museums suppressed; that loans to the museum should be insured and compensation paid in the event of damage; that the circulation section should be developed, greater care being taken in selecting objects, loans for three or four days being discouraged and cheap catalogues being provided; that a separate staff not liable to shuffling should be maintained for the Art Library, a special subject being added to the entrance examination, and the keeper being made in some way responsible for the library; that a board of visitors with clearly-defined status and functions should be established; that the elimination and selection of exhibits in the Science Museum should be carefully considered, circulation developed and the museum of fish culture abolished; and that Edinburgh Museum should have better exhibits and more free days, Dublin Museum should have a larger staff, and Bethnal Green Museum should have special treatment, a library, lecture-rooms and possibly a school being attached to it and good objects being sent there. In regard to the provision of offices in Whitehall, the removal of the Geological Museum from Jermyn Street to South Kensington, the total separation of the Science and Art Departments, and so on, Lord Balcarres is generally in accord with the chairman.

LORD LEIGHTON'S DRAWINGS.

THE collection of the late Lord Leighton's drawings and sketches now hanging on the walls of No. 2 Holland Park Road, which was for so long his residence, has lately been enlarged by the addition of more than 500 drawings, presented by Mrs. Sutherland Orr and Mrs. Matthews, Lord Leighton's sisters. It is chiefly owing to the generosity of these ladies that the collection has been secured for the public. Not only have they given by far the larger number of drawings, but they have also given help, without which the undertaking could not have been started. There are also on these walls a good many examples of Lord Leighton's painting. Mr. G. F. Watts, R.A., for instance, has given to the collection a painting much prized by him as having been presented to him by his friend many years ago. Among other contributors and among the members of the committee formed to secure the collection are the Prince of Wales, the Archbishop of Canterbury, the Archbishop of York, the Earl of Rosebery, the Bishop of London, the Bishop of Winchester, Lady Lyttelton, Lord Tennyson, Sir John Lubbock, Sir Henry Acland, Sir Alfred Lyall, Sir William Hunter, Sir Robert Hunter, Mr. Alfred de Rothschild, Mr. Leopold Rothschild, Sir W. Richmond, R.A., Mr. G. F. Watts, R.A., Mr. Alfred Waterhouse, R.A., Mr. Brock, R.A., Mr. Briton Riviere, R.A., Mr. MacWhirter, R.A., Mr. Frank Dicksee, R.A., Mr. Hamo Thornycroft, R.A., Mr. F. G. Jackson, R.A., Mr. George Aitchison, R.A., Mr. Holman Hunt, Mr. Walter Crane, Sir C. Hubert Parry, Herr Joachim, Mr. C. Villiers Stanford, Mr. Arthur Somervell, Mr. J. A. Fuller-Maitland, Mr. and Mrs. Russell Barrington, Mr. Lionel Cust and Mrs. Richmond Ritchie. Mr. Brock, R.A., has given a fine reproduction of his bust of Lord Leighton, which is placed in the hall of the house, while Lord Davey, Mr. A. Henderson, the Fine Art Society, Messrs. Agnew, Messrs. Colnaghi, Messrs. Tooth, Messrs. Cassell, the proprietors of the *Graphic* and others give reproductions of Lord Leighton's completed works. The Prince of Wales has presented to the collection the drawing *Summer Slumbers*.

ARCHITECTS' BENEVOLENT SOCIETY.

THE following report of the Council was adopted at the annual general meeting:—

The Council of the Architects' Benevolent Society, in presenting their annual report, have much pleasure in recording the fact that the progress in the Society's affairs during the past few years has been maintained in the year under notice. In view of the many calls upon the means of private individuals during the past year, the Council did not think it advisable that any special appeal on behalf of the Society should be made to the architectural profession; nevertheless, they have the satisfaction to report that many liberal donations have been received by the Society, and that several new names have been added to the list of subscribers.

Although the Society now possesses 300 annual subscribers, the Council feel that this number is not sufficiently representative of the large body of architects practising in the United Kingdom; they are assured that there must be a large number of architects, not subscribers to the Society, who would be desirous of helping their less fortunate brethren, or their widows and children who have been left insufficiently provided for. The usefulness of the Society would be increased in proportion to the augmentation of its list of subscribers; and the Council would remind those who have not contributed to the funds of the Society that an annual subscriber of one guinea has the privilege of recommending two applicants for grants during the year, and that relief is always afforded to worthy and properly accredited applicants when there are funds available for the purpose. It is earnestly wished that the list of annual subscribers should be increased, and members of the Society might materially help in effecting this object by bringing its aims and work under the notice of their brother architects.

The amount received in annual subscriptions during the year was 456*l.* 10*s.*, as against 453*l.* 8*s.* in 1896. Four members have withdrawn, and twelve members were in arrear with their subscriptions when the books were closed for the year, and the following gentlemen have recently become annual subscribers:—Sir Benjamin Baker, Messrs. J. Wallis Chapman, Charles Henman, Delissa Joseph, C. W. Lovett, E. W. Mountford, Alfred Williams, Latham A. Withall and Alfred B. Yeates.

The capital account has been increased by the bequests of 100*l.* each of Mr. David Mocatta and Mrs. Ann Mocatta, and by the following donations:—The Merchant Taylors' Company, 21*l.*; John o' Gaunt Sketching Club, 15*l.* 1*s.* 7*d.*; Mrs. C. E. Barlow, 12*l.*; Mr. Wm. Emerson, 6*l.* 13*s.* (thus bringing the total amount of his donations to 100*l.*); the Nottingham Architectural Society, 5*l.* 5*s.* The following gentlemen have each made a donation of five guineas:—Mr. J. T. Christopher, Mr. G. Elkington, Mr. George Inskipp, Mr. C. Henman, Mr. E. W. Mountford, Mr. W. Hilton Nash, Mr. J. Tavenor Perry; and various smaller sums have also been gratefully received.

At the beginning of the year there was a balance of 64*l.* 10*s.* 2*d.* to the credit of the capital account, and the amount of bequests and donations received during the year came to 300*l.* 17*s.* 7*d.* It was therefore decided to increase the Society's investments by the purchase of 200*l.* Caledonian Railway Four per Cent. Debenture Stock, and the purchase was effected at a cost of 311*l.*, thus leaving a balance to the credit of this account of 54*l.* 7*s.* 9*d.*

A larger number of applications for assistance than usual were made to the Society and considered by the Council. After proper investigation in each case the sum of 607*l.* 1*s.* (as against 569*l.* 10*s.* in 1896) was distributed amongst forty-three applicants, and 70*l.* was paid to the Society's three pensioners.

As the exertions of successive Councils for many years have

succeeded in bringing the amount of the invested capital up to 10,000*l.*, your present Council consider that the Society might now increase its present list of three pensions of not less than 15*l.* a year each to six pensions of not less than 20*l.* a year each. The approval of this step would, the Council think, add to the happiness of deserving applicants by the knowledge that they were to receive annually a certain sum. A motion to alter by-law No. 65 so that the above proposal may be carried into effect will therefore be submitted to you.

Following the example of recent years, the Red Book containing a revised list of subscribers, statement of accounts, &c., was issued last June to contributors to the Society and to the members of the Royal Institute of British Architects.

The Council have to record with deep regret the death during the year of Mr. W. J. Gardiner, Mr. Octavius Hansard, Mr. John Hudson, Mr. M. B. Teulon, Mrs. H. G. Mason, Mr. Stephen Salter, Mr. C. J. Shoppee, Mr. J. Loughborough Pearson, R.A., and Mr. Thomas Wells, all contributors to the Society.

Six meetings of the Council have been held during the year, the average attendance of members present being eight.

The following gentlemen, being the five senior members, retire by rotation from the Council :—Mr. William Kidner, Mr. George Scamell, Mr. Zeph. King, Mr. George Inskipp and Colonel Robert W. Edis. To fill the vacancies caused by these retirements, the Council have the pleasure to nominate Mr. E. W. Mountford, Mr. R. St. A. Roumieu, Mr. Wm. Woodward, Mr. E. B. I'Anson and Mr. E. H. Martineau.

The balance-sheet and income account for the year ended December 31, 1897, duly audited by Mr. Thomas Rickman and Mr. R. St. A. Roumieu, are herewith submitted.

The Council, in closing their report, desire to express the indebtedness of the Society to the Royal Institute of British Architects for the use of rooms in which to hold their meetings and to the officers for their always helpful courtesy.

HAWICK ARCHÆOLOGICAL SOCIETY.

THE members of the Hawick Archæological Society had their annual excursion on the 22nd ult. A company of over sixty, accompanied by the Rev. W. A. P. Johnman, president of the Society, left Hawick in the afternoon in brakes, and driving by way of Denholm and Ancrum Bridge, the company arrived at Monteviot, where, through the kind permission of Lord Lothian, they were allowed to walk through the grounds, and passing over the private bridge which spans the Teviot, the company were reseated and proceeded to Jedburgh. The abbey, Queen Mary's house, &c., were visited, and tea was served in the Spread Eagle Hotel, under the presidency of the Rev. Mr. Johnman. Continuing the drive, Ferniherst Castle, on the banks of the Jed, was reached, and arrangements having been previously made, the excursionists were allowed to inspect the interior of this ancient building, which is at present being renovated by Lord Lothian. The return journey was made by way of Swinnie and Bonchester.

THE NATIONAL GALLERY.

THE following additions have been recently made to the National Gallery :—

Bequeathed by Miss Haines.—"A Landscape," by George Lambert, a painter of the English school of the last century. It is placed temporarily on a screen in Room XVIII.

Bequeathed by Mrs. Charlotte Fisher.—"The Battle off Camperdown, 1797," by Thomas Whitcombe. This will shortly be placed in the entrance hall on the eastern staircase descending to the Turner rooms.

Presented by the Right Hon. Sir Edward Malet, G.C.B.—A portrait of Adrian van der Werff, by himself. Hung in Room XI.

Presented by an anonymous donor.—A "Madonna and Child," by Luigi Vivarini. This picture is of interest as bearing the signature of the artist, but as it is not of sufficient value as a work of art to be placed in the Gallery, it is hung, with the consent of the donor, in the waiting-room to the offices.

Presented by Dr. E. J. Longton.—A water-colour copy by W. West of a portrait of a lady and child by Vandyke, forming part of the series of copies presented by the same donor in 1886.

The following have been purchased :—

The two wings of the altar-piece of which the "Vierge aux Rochers," now in the National Gallery, formed the central portion. They represent angels playing on musical instruments, and were painted by Giovanni Ambrogio de Predis in conjunction with Leonardo da Vinci, who did the central composition. One of these, No. 1,661, was apparently begun by Leonardo himself and carried out by the pupil; the other, No. 1,662, seems to be entirely the work of Ambrogio—they are temporarily framed and placed on a screen in Room No. VI. during the repairs which are going on in No. I.; a portrait by Hogarth of his sister, Mrs. Salter, hung in Room XIX.; and a picture by J. B. S. Chardin, called "La Fontaine," placed in Room XVI.

AN ANCIENT ROMAN HOSPITAL IN SWITZERLAND.

THE Zurich correspondent of the *Times* writes :—An ancient Roman hospital has been brought to light at Baden, near Zurich, the discovery having been made in conection with recent excavations at Windisch, the Roman Vindonissa. At Vindonissa the two great Roman roads met, the one leading from the Great St. Bernard along Lake Leman and then by Aventicum and Vindonissa to the Roman stations ou the Rhine; the other leading from Italy to Lake Constance by the Rhætian Alps, the canton which is now Winterthur, Baden and Windisch. The last point was the station of the seventh and eighth legions, and close by the Roman road the hospital has been discovered. It contains fourteen rooms supplied with many kinds of medical, pharmaceutical and surgical apparatus, the latter including probes, tubes, pincers, cauterising instruments and even a collection of safety pins used in bandaging wounds. There are also medicine spoons in bone, and silver measuring vessels, jars and pots for ointment, some still containing traces of the ointment used. The excavations have also revealed a large number of silver and copper coins, the former belonging to the reign of Vespasian and Hadrian, and the latter bearing the effigies of Claudius, Nero and Domitian.

THE EDINBURGH COCKBURN ASSOCIATION.

AT a meeting of the Council of the Cockburn Association, held on Friday, June 24, the following resolution was arrived at :—"That while in the opinion of the Council it was premature to commit the Association to a decision as to the merits of the various sites for the Usher Town Hall to be considered by the Town Council, the secretary be instructed to intimate to the town clerk that the general feeling of the Council was strongly opposed to the recommendation of the Lord Provost's committee to erect the hall at the west end of the West Meadows, and to suggest that the area proposed to be taken should be clearly staked off before that recommendation should be adopted." The secretary intimated that he had received a letter directing the attention of the Association to the dilapidated condition of the memorial monument to Miss Catherine Sinclair at the corner of North Charlotte Street and St. Colme Street, and he was instructed to endeavour to arrange for its restoration and future maintenance. Upon the letter directing attention to an unsightly brick building overlooking Market Street to the east of the Cockburn Hotel, it was remitted to the convener, with the secretary, to inquire into the matter, and to take such action as might seem desirable.

ROYAL INSTITUTE OF BRITISH ARCHITECTS.

THE subjoined schedule sanctioned by the Royal Institute of British Architects was confirmed at a general conference of architects of the United Kingdom, 1872, and revised by the Royal Institute 1898 :—

1. The usual remuneration for an architect's services, except as hereinafter mentioned, is a commission of 5 per cent. on the total cost of works executed under his directions. Such total cost is to be valued as though executed by a builder with new materials. This commission is for the necessary preliminary conferences and sketches, approximate estimate when required (such, for instance, as may be obtained by cubing out the contents), the necessary general and detailed drawings and specifications, one set of tracings, duplicate specification, general superintendence of works, and examining and passing the accounts, exclusive of measuring and making out extras and omissions.

2. This commission does not include the payment for services rendered in connection with negotiations relating to the site or premises, or in supplying drawings to ground or other landlords, or in surveying the site or premises and taking levels, making surveys and plans of buildings to be altered, making arrangements in respect of party-walls and rights of light, or for drawings for and correspondence with local and other authorities, or for services consequent on the failure of builders to carry out the works, or for services in connection with litigation or arbitration, or in the measurement and valuation of extras and omissions. For such services additional charges proportionate to the trouble involved and time spent are made. The clerk of the works should be appointed by the architect, his salary being paid by the client.

3. In all works of less cost than 1,000*l.*, and in works requiring designs for furniture and fittings of buildings, or for their decoration with painting, mosaics, sculpture, stained-glass

or other like works, and in cases of alterations and additions to buildings, 5 per cent. is not remunerative, and the architect's charge is regulated by special circumstances and conditions.

4. When several distinct buildings, being repetitions of one design, are erected at the same time from a single specification and one set of drawings and under one contract, the usual commission is charged on the cost of one such building, and a modified arrangement made in respect of the others; but this arrangement does not apply to the reduplication of parts in one building undertaking, in which case the full commission is charged on the total cost.

5. If the architect should have drawn out the approved design, with plans, elevations, sections and specification, the charge is 2½ per cent. upon the estimated cost. If he should have procured tenders in accordance with the instruction of his employer, the charge is ½ per cent. in addition. Two and a half per cent is charged upon any works originally included in the contract or tender, but subsequently omitted in execution. These charges are exclusive of the charge for taking out quantities. Preliminary sketches and interviews, where the drawings are not further proceeded with, are charged for according to the trouble involved and time expended.

6. Should the client, having approved the design, and after the contract drawings have been prepared, require material alterations to be made, whether before or after the contract has been entered into, an extra charge is made in proportion to the time occupied in such alterations.

7. The architect is entitled during the progress of the works to payment by instalments on account at the rate of 5 per cent. on the amount of the certificates when granted, or alternatively on the signing of the contract to half the commission on the amount thereof, and the remainder by instalments during their progress.

8. The charge per day depends upon an architect's professional position, the minimum charge being three guineas.

9. The charge for taking a plan of an estate, laying it out, and arranging for building upon it is regulated by the time, skill and trouble involved.

10. For setting out on an estate the position of the proposed road or roads, taking levels, and preparing drawings for roads and sewers, applying for the sanction of local authorities, and supplying all necessary tracings for this purpose, the charge is 2 per cent. on the estimated cost. For subsequently preparing working drawings and specifications of roads and sewers, obtaining tenders, supplying one copy of drawings and specification to the contractor, superintending works, examining and passing accounts (exclusive of measuring and valuing extras and omissions), the charge is 4 per cent. on the cost of the works executed, in addition to the 2 per cent. previously mentioned.

11. For letting the several plots in ordinary cases the charge is a sum not exceeding a whole year's ground-rent, but in respect of plots of great value a special arrangement must be made.

12. For approving plans submitted by the lessee, and for inspecting the buildings during their progress, so far as may be necessary to insure the conditions being fulfilled, and certifying for lease, the charge is a a percentage not exceeding 1¼ per cent. up to 5,000*l.*, and above that by special arrangement.

13. For valuing freehold, copyhold, or leasehold property, the charge is—

On 1,000*l.*	. . .	1 per cent.
Thence to 10,000*l.*	. . .	½ „
Above 10,000*l.*	. . .	¼ „ on residue.

In valuations for mortgage, if an advance is not made, one-third of the above scale. The minimum fee is three guineas.

14. For valuing and negotiating the settlement of claims under the Lands Clauses Consolidation Act or other Acts for the compulsory acquisition of property, the charge is on Ryde's scale, as follows :—

On Amount of Settlement, whether by Verdict, Award or otherwise.

Amount.	Gs.	Amount.	Gs.	Amount.	Gs.	Amount.	Gs.
£		£		£		£	
100	5	2,200	24	5,200	39	8,200	54
200	7	2,400	25	5,400	40	8,400	55
300	9	2,600	26	5,600	41	8,600	56
400	11	2,800	27	5,800	42	8,800	57
500	13	3,000	28	6,000	43	9,000	58
600	14	3,200	29	6,200	44	9,200	59
700	15	3,400	30	6,400	45	9,400	60
800	16	3,600	31	6,600	46	9,600	61
900	17	3,800	32	6,800	47	9,800	62
1,000	18	4,000	33	7,000	48	10,000	63
1,200	19	4,200	34	7,200	49	11,000	68
1,400	20	4,400	35	7,400	50	12,000	73
1,600	21	4,600	36	7,600	51	14,000	83
1,800	22	4,800	37	7,800	52	16,000	93
2,000	23	5,000	38	8,000	53	18,000	103
						20,000	113

Beyond this Half a Guinea per cent.

The above scale is exclusive of attendances on juries or umpires, or at arbitrations, and also of expenses and preparation of plans.

15. For estimating dilapidations and furnishing or checking a schedule of same, the charge is 5 per cent. on the estimate, but in no case less than two guineas. For services in connection with settlement of claim by arbitration or otherwise, extra charges are made under clause 8.

16. For inspecting, reporting and advising on the sanitary condition of premises, the charge must depend on the nature and extent of the services rendered.

17. In all cases travelling and other out-of-pocket expenses are paid by the client in addition to the fees. If the work is at such a distance as to lead to an exceptional expenditure of time in travelling, an additional charge may be made under Clause 8.

18. When an architect takes out and supplies to builders quantities on which to form estimates for executing his designs, he should do so with the concurrence of his client, and it is desirable that the architect should be paid by him rather than by the builder, the cost of such quantities not being included in the commission of 5 per cent.

Among those taking part in the debate on the revised schedule at the meeting of the Institute on Monday were Messrs. E. A. Gruning, J. Douglass Mathews, H. Heathcote Statham, John Slater, C. Forster Hayward, Edmund Woodthorpe, W. Hilton Nash, S. Flint Clarkson, Wm. Woodward, Hampden W. Pratt, A. W. Tanner, H. Hardwicke Langston, C. B. Brodie, W. H. Atkin Berry, Zeph. King, Max Clarke and others.

At the close of the proceedings a vote of thanks was carried by acclamation to the practice standing committee for their labours in carrying out the revision.

TESSERÆ.

Gothic and Classic.

THOSE who censure the Gothic as an incoherent style, full of inconsistencies and caprices, as devoid of all harmony and proportions, and as a gloomy monkish mode of building, may be allowed to pique themselves on their fastidious classical taste, but certainly not on either their poetical sensibility or their philosophical discrimination. That both its proportions and its principles are widely different from those of Grecian architecture is self-evident; that the one is therefore incorrect, and the other deficient in harmony, is exceedingly easy to be asserted, yet exceedingly difficult to be demonstrated. So very far indeed is the Gothic style from being altogether arbitrary and inconsistent, that no one can give it attention with an unprejudiced mind without perceiving what consummate skill and beautiful intention of purpose, what invention, guided by true artistlike feeling, are to be distinctly traced throughout. So far it may lay claim to the greatest consistency. The mixture of different styles in the same edifice is a mere casual circumstance, not in the least detracting from the coherence and consistency of any one style taken by itself. Yet is not Salisbury Cathedral nearly uniform throughout as to style, and King's College Chapel completely so? Another error very frequently entertained is that, however suitable for buildings upon a large scale, the Gothic style is but ill adapted to small ones. Undoubtedly its most astonishing effects and displays of grandeur must be in spacious edifices; yet that it possesses also many delicate beauties and graceful forms, capable of being fully displayed in smaller works, will be disputed by none who have ever entered some of our Gothic chantries and small chapels, or have seen if only in a drawing the beautiful little cloister of St. Stephen's Chapel.

Jones's Design for the Whitehall Palace.

The chief defect in the ideal palace which Jones designed seems to be the absence of some central point, or crowning object of attraction, to connect and combine the whole. There are four fronts, each in itself complete, and squares and towers and domes; but as a whole it looks more like a city for merchants than a palace in which princes are to reside. If there is not too much uniformity in the elevations, there is certainly considerable uniformity in the mode of treating them. Rusticated walls, with rusticated columns and pilasters, abound, giving a heavy look to the whole lower storey, which the wonderful beauty and perfect symmetry of the second cannot lighten. Those rusticated courses of stone, frosted columns and imitations of coral rocks are only fit for gathering filth, and should be reserved for bridges, piers and basins. Nor can a good defence be offered for placing two, nay, three rows of columns over one another as they appear in the banqueting-house and in the whole of the original design of the palace. To place the heavy bases of one order upon the slender capitals of another seems questionable architectural heraldry. In an ancient temple the columns stand on the

ground, and supporting the roof of the structure all about, afford shelter by their distance from the wall to those who seek protection from a scorching sun. The Greeks and Goths always had a meaning in their works; the close cloisters of the one correspond with the open columns of the other; the Grecian shades from the heat, the Gothic from the cold, and both suit their climates; but of what use are the columns of Whitehall? Rank stands above rank, but they support no roof; they relieve not by the depth of their shadow the weight of the impending walls, nor do they stand far enough from the body of the building to give shelter from either sunshine or rain. The statues and reliefs which Inigo introduced to give effect to his elevations are beyond all examples numerous, but except those in the Persian court they are not defined enough to show the meaning of the artist. On the Westminster front alone there appear 176 statues, erect or recumbent, nor are they less plentiful on the other fronts. On the towers can be seen none of those winged cherubim of which Walpole complains, but figures which, from look and posture, are doubtless intended for gods, others which may pass for kings and statesmen, priests not a few, and many warriors. They serve to interrupt and diversify the uniform line of the summit, and with their plinths and pedestals to conceal the roofs, which in an extent of 4,000 feet in circuit too frequently intruded their ridges upon the sight. Such an extent of plain-ridged roof must have been offensive to an eye so tasteful as that of Jones, who could not but feel that though the balustrades concealed it from the spectator in the immediate neighbourhood, its barren uniformity must needs be visible in the distance. He might have studied the ancients on this particular matter to better advantage. "Few roofs," says Payne Knight, "of ancient buildings remain; in them, however, a peculiar attention seems to have been paid both to regularity of construction and to light and shadow. The Tower of the Winds at Athens is covered with slabs of marble, in each of which the horizontal edge projects so much as to give a strong shade, while the vertical joints are so elevated as to form high ribs which break the uniform surface in a very beautiful manner. The Lantern of Demosthenes is roofed in the form of laurel leaves, which in a different way have the same effect. The ancients seem to have had it in view to give both lightness and richness to their roofs by a sort of lacing on the edges of them; the ridges, as well as the eaves, were decorated with a sort of open work of small knobs and projections; and the same kind of ornament still remains with peculiarly elegant effect in many of our old churches and houses." It must not, however, be disguised that unless the roofs are very steep, these ornamental lacings in a humid climate like ours would lodge the sleet and the rain, and render the substructure damp: here they are always employed on roofs which rise considerably above the square. With many blemishes, but for every blemish a dozen beauties, the Whitehall Palace, for grandeur of conception and elegance of interior arrangement, was more than worthy of the age it was designed in, and exhibited altogether a solid magnificence which might be compared with any royal palace on earth.

Artist's Self-praise.

The artist should talk as little as possible of his own works, much less to praise them, and this not so much for the sake of avoiding the character of vanity as for keeping clear of a real detriment, of a real productive cause which prevents his progress in his art and dulls the edge of enterprise. He who has the habit of insinuating his own excellence to the little circle of his friends with whom he comes into contact will grow languid in his exertions to fill a larger sphere of reputation. He will fall into the habit of acquiescing in the partial opinions of a few; he will grow restive in his own; by admiring himself he will come to repeat himself, and then there is an end of improvement. In a painter it is particularly dangerous to be too good a speaker; it lessens the necessary endeavours to make himself master of the language which properly belongs to his art, that of his pencil. The circle of self-applause and reflected admiration is to him the world which he vainly imagines he has engaged in his party, and therefore supposes that further enterprise becomes less necessary. Neither is it prudent, for the same reason, to talk much of a work before he undertakes it, which will probably thus be prevented from being ever begun. Even showing a picture in an unfinished state makes the finishing afterwards irksome; the artist has already had the gratification which he ought to have kept back and made to serve as a spur to hasten its completion.

Adam's Architecture.

The style of architecture introduced by Adam Brothers was peculiar to themselves and very faulty; but there is nevertheless an air of prettiness and some good taste in it, and the credit may certainly be claimed for its authors of having done much to improve the street architecture of London, for which species of composition their style was better adapted than fo detached and insulated structures. Their taste seems to hav been slightly affected, and in that slight degree beneficially, b the Greek style of composition which Stuart and Revett were then making known, but they certainly were far from entering into the spirit of it; they departed, moreover, almost entirely from the laws and usages of the Italo-Vitruvian school, which was then called Classical, and introduced many deviations alike inconsistent with the styles of Greece and Rome, with the laws of the schools, and with sound sense and good taste. The entire omission or contraction of an architrave in their entablatures, the extravagant breadth of their friezes, the shallowness and almost universal meanness of their cornices, and the still meaner and more tasteless style of the decorative ornament with which they beplastered their friezes and ceilings, are among the most glaring faults of their peculiar manner. In their insulated compositions especially the worst of these faults are aggravated by varieties of them being introduced, not only into different but also into the same elevations of the same structures, which should at least harmonise even in their defects. Both Kenwood and Luton Houses were examples of this; they both had mean entablatures, which were differently composed and proportioned, on the same and on different fronts of the respective edifices. In mere street fronts the style of the Brothers Adam is not only less offensive, but it is at times made even pleasing.

GENERAL.

MM. Legros have obtained the Prix Bailly from the Académie des Beaux-Arts for the hospital designed by them, which was founded by the late Madame Boucicaut.

The Slade Professorship of Fine Art will shortly be vacant. Candidates are requested to send in their names to the Registrar of the University on or before Thursday, July 7.

The National Swiss Museum, established in Zürich for the archæological collections of the Confederation, was inaugurated on Saturday last in presence of the Federal Council and others.

Commander Wells, R.N., has prepared a handy "Manual of Fire Drill," which will be of use to establishments where there is an organisation for overcoming outbreaks of fire.

An Engraving after Reynolds's "Mrs. Pelham feeding Chickens," by W. Dickinson, was sold on Monday for 425 guineas. For "Lady Hamilton as a Bacchante" the price given was 51 guineas.

The Municipal Council of Paris have purchased works of the value of 63,750 francs from the two exhibitions in the Champ de Mars.

The Middlesex County Council have decided to appoint Mr. Henry T. Wakeman, of Hereford, as county surveyor, on the following conditions:—(1) The salary to be at the rate of 700*l.* a year, rising to 850*l.* a year by annual increments of 25*l.* (2) Travelling expenses, when necessary in connection with the duties of the office, to be allowed on a scale to be fixed by the County Council. (3) To his being an associate member of the Institution of Civil Engineers. (4) To his devoting the whole of his time to the duties connected with the appointment.

An Exhibition of students' work in the various crafts taught in the Central School of Arts and Crafts, at 316 Regent Street, will be opened on Monday next and remain open throughout the week.

Mr. M. Garton, a brewer, has offered to complete the new wing of the Royal South Hants Infirmary at a cost of considerably over 5,000*l.* This wing was to have been Southampton's Jubilee Memorial, but the funds raised to carry out the project were altogether insufficient. Mr. Garton had previously contributed 2,000*l.* towards the same object.

The Primitive Methodists have during the past year erected fifty new places of worship for members of the connexion, affording accommodation for 12,235 persons. Towards the cost of 55,805*l.*, the sum of 25,603*l.* was contributed. The debt on connexional trust property now stands at 1,094,753*l.*, or more than 1*l.* per sitting, the total accommodation being for 1,020,924 persons.

The Governors of Christ's Hospital obtained an order on Saturday for the paying out of 34,000*l.* received from the Postmaster-General as purchase money for No. 10 King Edward Street, which is to be applied towards payment of the cost of the new buildings now in course of erection at Horsham, which, exclusive of site, was stated to be 294,243*l.*

The First Prize of 25*l.* in the public competition for the best plan for laying out the new Victoria Park at Tipton has been unanimously awarded to Messrs. William Barron & Son, Borrowash. Their plan shows a lake about 3 acres in extent, cricket and recreation grounds, lawn-tennis grounds, bowling green, band stand, shelters, &c. They also furnish plans for lodge, entrance gates, ornamental fencing, &c. The park is 33 acres in extent. The second prize was awarded to Mr. John Perry, architect, Tipton. There were ten competitors.

THE

Architect and Contract Reporter.

IMPORTANT NOTICE.

WORKMEN'S COMPENSATION ACT.

In view of the many difficulties which are certain to arise in connection with the law, practice rules and procedure under the above Act, we have added to our staff A VERY EMINENT BARRISTER, who has made the subject a special study, and will be glad to answer in the columns of this paper any questions relating to the complicated matters arising from the provisions of this difficult Act. Our LEGAL ADVISER will further answer any legal question that may be of interest to our readers. All letters must be addressed "LEGAL ADVISER," Office of "The Architect," 175 Strand, London, W.C.

COMPETITIONS OPEN.

THE foundation-stone of a new Baptist chapel at Ferme Park, Hornsey, was laid on Monday. The present building, which seats some 600 persons, was erected about ten years ago. But the neighbourhood has so greatly increased that it has been determined to erect a new chapel to seat 1,150 persons; the present building, which is contiguous, will be then used as a school and lecture-hall. The site for the new building has cost 860*l.* The cost of the chapel, exclusive of this sum, but including the new organ, will be 9,700*l.* The general plan will be a Greek cross, with wood vaulted ceiling, and the style a late period of Gothic architecture. It will be faced with red brick, with warm buff terra-cotta dressings, and at one corner there will be a tower with curving roof. The architect is Mr. George Baines.

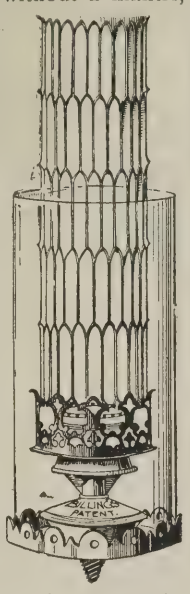
A PERMANENT exhibition of manufactures and machinery is now open in Lima, in the machinery hall of the Exhibition Palace, under the auspices of the Government of Peru, and under the management of the National Society of Industry. No charge is made for space, no duties on exhibits, and many privileges are accorded to exhibitors, and, as is well known, Peru offers a splendid field for the extension of British trade. Full particulars can be obtained from Mr. E. Lembeke, consul-general, 237 Winchester House, E.C.

ELECTRIC NOTES.

THE Great Western and London and North-Western Railway Companies have petitioned the House of Commons to be allowed to withdraw their opposition to the Shrewsbury Electric Lighting Bill.



A FIRE broke out in the early morning of the 28th ult. on the premises of the electric-light works in South Street, Manchester Square. Four steamers were soon on the spot, and with an excellent supply of water available the flames were eventually got under, not, however, before serious damage had been done.

AT last Friday's meeting of the Court of Common Council at the Guildhall, the Lord Mayor, M.P., presiding, Mr. Brooke Hitching moved that it be referred to the streets committee to consider and report as to the desirability of approaching the City of London Electric Light Company, Limited, with a view to the acquisition by purchase of so much of that company's undertaking and plant as is situated within the City, together with the company's electric light generating station in Southwark. He said the Corporation was not the only municipality in the kingdom which had committed the initial mistake of entrusting the electric lighting of their area to private enterprise, but Liverpool and other places had repaired the mischief and the loss to the ratepayers by purchasing the undertakings of the companies supplying their cities. His motion was one simply of inquiry, whether the company were disposed to sell their rights, and if so, at what price. Mr. Turner seconded the resolution. Mr. A. A. Wood was convinced that the City Commission of Sewers, to the extent of their knowledge at the time, did the best they could, in the interests of the citizens, in their negotiations with the company. Mr. A. C. Morton said the City Commission of Sewers were "bamboozled" and led astray by unholy influences in their own body. If the matters could be revealed, it would be interesting to see the large sums made by City people—including a former Lord Mayor—out of the matter. He deprecated rushing into the arms of the company. The City Solicitor, replying to a question, said the company's exclusive rights as to private lighting would expire in 1911 and 1912. Mr. Brooke Hitching's motion was withdrawn in favour of a resolution by Mr. Deputy Johnson, sending the whole question of the electric lighting of the City to the streets committee for consideration and report.

A MANTLELESS INCANDESCENT GAS-BURNER.

THE latest method of obtaining the maximum amount of illumination with the minimum consumption of gas is that provided by Billing's Non-Mantle Burner Syndicate, of 180 Wardour Street, W., in their new gas-burner, which, without a mantle, gives an incandescent flame of great brilliancy and soft, pleasant colour, practically smokeless, and with very little heat, and that little is utilised to warm the gas before ignition, by which process perfect incandescence is insured. To secure this result two chimneys are used, as shown in sketch. The air, instead of being supplied to the flame at its normal temperature, is drawn down between the outer and the inner chimneys by the action of the flame, which it reaches in a heated condition, when it combines readily with the gas and produces the acknowledged desideratum—perfect combustion. It may be thought that the use of two chimneys may occasion considerable expense in replacement, but this is not so, as the fact that the air is drawn between the two chimneys, and thus heated as above described, prevents the breaking of the glass, which is so great a drawback in burners of the ordinary circular type. In short, the advantages of the new burner may be summarised as follows:—Brilliancy and agreeableness of light purity; of the atmosphere, as there is no smoke or odour; the burner is made on scientific principles, and whether the gas be rich or poor in carbon, the whole of such carbon is by it made incandescent; economy in the consumption of gas, as a burner giving a 32 candle-power flame consumes only 5 feet of gas per hour; ornamental appearance, a wide range of variety in shades and glasses having been especially designed for decorative effect; and finally, although not of least moment, the initial cost is small.

THERE was a large attendance on Wednesday at the laying of memorial-stones for a new school-chapel in Corporation Road, Darlington. The district is a new one, and hence the need of more accommodation. The building is to accommodate bout 500, and will cost 1,200*l.*

VARIETIES.

AN excursion meeting of the Northern Architectural Association will be held to-morrow, July 2.

THE annual congress of the British Archæological Association will this year be held at Peterborough, where the proceedings will open on the 14th inst.

A NEW Board school was opened at Ketley on Monday last. It was built at a cost of 2,800*l.* to accommodate 220 children, and the infants' school 140.

THE official ceremony of the opening of the Guildhall School of Music extension by the Lord Mayor will take place on Monday week.

A FACTORY chimney was being demolished at Rochdale when it fell amongst a crowd of 2,000 people, several of whom were seriously injured.

NEW Jerusalem Church, Accrington, having been closed for nearly twelve months for renovation, has again been opened for service.

THE restoration of Salisbury Cathedral spire is now completed, and the event will be celebrated by a thanksgiving service on the 11th inst. The cost of the work is 15,000*l.*

THE Bradford Association of Architects visited Pateley Bridge on Tuesday, and saw the extensive works in the valley in connection with the Bradford water supply.

MR. A. SAXON SNELL has been instructed by the West Ham Corporation to prepare plans for the erection of public swimming and private baths and other buildings in Romford Road, Stratford, E. (opposite the new technical institute).

THE new laboratories at University College, Liverpool, which have been erected and equipped by the Rev. S. A. Thompson Yates for study and research in physiology and pathology at a cost of over 25,000*l.*, will be formally opened on October 8 by Lord Lister.

IN the parish church at Windsor, on Sunday, a carved oak chancel screen, subscribed for by the parishioners and erected from the designs of Sir Arthur Blomfield, A.R.A., as a Diamond Jubilee memorial, was dedicated by the Bishop of Oxford in the presence of Prince and Princess Christian.

THE residents of Dean Street, Ashton, near Manchester, were recently startled by the complete collapse of a large brick building, formerly owned by Mr. R. Atkinson. The furniture inside was shattered, and *débris* was scattered in all directions.

Manufacturers:—HUGHES & LANCASTER, 16 Great George Street, Westminster, London, S.W.

The structure has not been in use for some years. It is supposed the woodwork had become rotten. Fortunately there were no people in the vicinity.

A NEW free library and reading-room were opened for public use at Denton on Monday. The new premises, along with the technical school—which is not quite finished—form part of a fine, centrally situated block of buildings in Peel Street, and have cost about 4,500*l.* The new buildings are electrically lighted throughout. There are over 3,000 volumes in the library. The premises in Market Place, which have been used for technical instruction, free library and reading-room purposes since they were erected in commemoration of the 1887 Jubilee of Her Majesty, are to be converted into a town hall, and will shortly be opened.

THE Japanese twin-screw steamer, *Sadu Maru*, went on a trial trip on the Clyde on the 6th inst. She was built by Messrs. Workman, Clark & Co., Limited, of Belfast, to the order of Capt. A. R. Brown, for the Nippon Yasen Kaisha of Tokio, Japan. This vessel will be used for trading between Great Britain and Japan, and is classed 100 A1, three decks rule, deadweight capacity 7,600 tons. She is fitted up throughout by mechanical ventilation by compressed air on improved principles, the same being applied to the holds, between decks, stokeholds, engine-rooms and saloons. The contractors were the well-known ship-ventilating firm, Messrs. Grahtryx Ventilating and Engineering Company, Limited, 23 Sutterton Street, Caledonian Road, London, N., and 20 Union Street, Glasgow, and is the twelfth ship fitted for the same company. The system of ventilation was a special feature at the trial, which was favourably commented on and highly satisfactory to the owners.

THE chimney-stack upon the premises of Messrs. Buckton & Co., linen manufacturers, Goodman Street, Hunslet, was struck by lightning on Sunday last. The bricks were thrown a distance of 80 yards to the other side of Goodman Street and smashed a number of windows in adjoining factories. The roof of a bleaching house at the foot of the chimney was completely wrecked. Fortunately, no one was in the street at the time, or a fatality would certainly have resulted. Immediately after the lightning had struck it the chimney presented an extraordinary spectacle. There were three extensive rents in it, one at the left corner facing Goodman Street and the other two on the right side. A telephone wire communicating with the office was attached to the chimney, and it is supposed that the insulator had attracted the lightning. The wire has been smashed into innumerable pieces. The chimney, which is 95 feet high, is a square one, built as many as thirty years ago, and was not supplied with a lightning conductor. It will now have to be pulled down.

BUILDING AND BUILDERS.

THE memorial-stones of a new Wesleyan chapel at Monton, near Eccles, have been laid. The estimated cost of the building is 1,350*l.*, and seating accommodation will be provided for about 250 persons.

THREE corner-stones of the chancel to be added to St. Bartholomew's Church, Marsden, erected four years ago, have been laid. It is estimated that the chancel and the tower will cost 9,000*l.*

PLANS have been accepted for the erection of a mission hall on the vacant site adjoining the church in Dalrymple Street, Stranraer. The plans show a suitable structure, which will be erected at a cost of upwards of 300*l.*, with seating accommodation for 250.

THE foundation-stone of a new English church has just been laid at Düsseldorf. It will be a pretty Gothic structure, seating about 200 people, and is an offering from a resident family, who for many years have taken a keen interest in the English community of the place.

THE sites are now being cleared for two more additions to London's outlying places of amusement. One is in Holloway Road, nearly opposite Holloway Hall, on which is to be erected the local Empire Theatre of Varieties, and the other in a more central position in the Euston Road, opposite the Midland Grand Hotel. This is to be known as the Euston Theatre of Varieties.

THE foundation-stone of the new theatre in the Birmingham Road, Dudley, was laid on the 27th ult. The site is close to the railway station and the termini of four tramway systems, and adjoining the boundary of the castle. The theatre is being built by Mr. J. Maurice Clement, the proprietor of the existing Colosseum theatre, and the cost is estimated at over 16,000*l.*, including nearly 3,000*l.* for the land and 11,000*l.* contract for the building. Mr. A. Ramsell is the architect, and Messrs. J. H. Whittaker & Co. are the contractors.

MACKIE'S PATENT "DEFIANCE" HYDRAULIC WATERTIGHT FLOOR SPRING AND CHECK.

Size of Plate, 12 × 8 in.
Size of Box, 10¾ × 6 × 5¾ in.

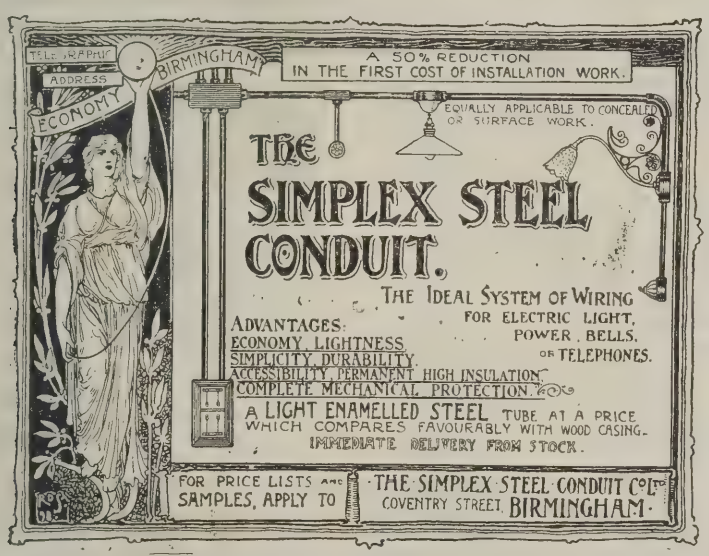
906
80/-
With top centre and brass shoe any size.

This Floor Spring is suitable for any sized door, and can be regulated to suit any force required.

The box is watertight and weatherproof, a distinct advantage when fixed in Banks, Board Schools, Libraries, and similar places, where the floors are frequently washed down.

It is also sent complete with an outer box to fix into floor, to facilitate the spring being taken out when necessary.

Working Models of these and other Specialties may be seen at our newly-fitted London Showrooms, 57 HOLBORN VIADUCT E.C.
Architects and Buyers are respectfully invited to inspect same.



A LARGE building, with a frontage of 250 feet, is to be erected at Mazenod Avenue, Hampstead, to be called Priory Court, and arranged as residential flats. The site is elevated about 4 feet above the road in front, and the building will be set back with returning wings right and left. The elevation will be Georgian in style, with gauged brick arches and aprons, surmounted with a heavy stone cornice, while green Venetian shutters, ornamental garden court and fountain will have a quiet and retiring effect. The architects are Messrs. Palgrave & Co., Westminster, S.W.

COLDBATH FIELDS prison, which is now being pulled down, was on Tuesday the scene of an accident by which several men were severely injured. They were working on the top floor breaking down the structure, when the concrete flooring gave way and carried the lower floors with it. Two of the men fell with it, a distance of over 50 feet. They were conveyed to the hospital, where it was found that Edward Morgan, aged thirty, had a compound fracture of the left ankle, and that his right leg was badly crushed and his head and face severely cut. John Ford, aged 58, had injuries to his ribs and shoulder. After Ford's injuries had been dressed at the hospital he was allowed to go home, but Morgan was so seriously injured that it was found necessary to detain him as an in-patient.

AN important building situated in Moor Street, Birmingham, and erected for Messrs. Coleman & Oldland, wholesale clothiers, is now completed. This structure has a good frontage and is five storeys in height. A large basement forms the cutting-room, the ground floor the shop, which is elaborately fitted up, the remaining floors being the general workrooms. The walls and ceilings of basement and ground floor are covered with stained and varnished matchboarding. There is ample light to each floor both at front and back of building, and adequate ventilation has been provided. The building is of substantial construction, steel girders, cast-iron columns, &c., having been used. The heating apparatus is of the most efficient and modern kind; a spacious lift, running from basement to top floor, is provided, and the building is illuminated by the electric light. The front elevation is chiefly of best red brickwork, with ornamental cornice and strings, large cast-iron windows, two entrance doors and wide gates, stone heads, sills, columns, &c. The architect is Mr. John Statham Davis, of Cobden Buildings, Corporation Street, and the contractor Mr. William Hopkins, of Thorpe Street, both of Birmingham.

THE memorial-stone has been laid of Wellfield United Presbyterian church, Glasgow. The church in question is situated at the corner of Balgray Hill and Murdoch Street, and extends back to Sutherland Street. The very rapid fall of the ground on the hill-side has added considerably to the difficulties of planning, there being a difference of over 27 feet between the levels of the back street and the lower point on Balgray Hill. To meet this the hall has been placed facing Sutherland Street, on the higher level, and entering from Murdoch Street, the rooms, vestry, sessions house, &c., on an intermediate level, while the church occupies the corner of Murdoch Street and Balgary Hill. Internally the church is planned with nave and side aisles, which are separated by moulded stone arches carried on splayed stone piers. There are galleries at sides and end, but the galleries are kept back behind the line of the stone piers, allowing these to be carried up in an unbroken line. Above the piers attached stone shafts are carried up, terminating in carved caps, from which spring the principal roof couples. The pulpit will be placed under a wide stone arch at the eastern end, and on each side, under smaller arches, an organ chamber is arranged. The hall is 54 feet long and 28 feet broad, and there are two large classrooms, which can be opened into one, forming a lesser hall for 100 persons. The style of architecture is Gothic of the Late Decorated period, and the principal feature externally will be the tower and spire, which will be over 100 feet high. The lower stage is carried up square to the belfry chamber, where the plan becomes octagonal, with projected buttresses at the angles of the tower. The principal front to Balgray Hill has the main gable in the centre, flanked by the tower on one side and a projecting staircase on the other. The mason-work is in red sandstone, and is already well advanced, the memorial-stone being placed in the western face of the tower at the gallery floor level. The number of sittings provided is 808, and the expected cost of the whole scheme is about 7,200*l.* The architect is Mr. John B. Wilson, Glasgow.

THE enormous new London coal depôt of the Midland Railway Company in Somers Town covers six acres of ground—a huge slice out of the once densely populated working-class neighbourhood in which it is situated—and whole streets of houses have been swept away at an expenditure of many thousands, especially for compensation, to make room for it. It lies immediately behind the great goods depôt of the Midland in the Euston Road. It has been built at a cost of 180,000*l.*, the contract for the foundations and brickwork being 80,000*l.*, and for the iron and steel-work 100,000*l.* The depôt consists of a vast roofed-in space of great length and breadth, without

any subdivisions. At certain intervals are placed 132 iron pillars, each 18 feet high and of proportionate diameter. These support 139 main girders, each weighing close upon 14 tons, and a number of cross girders, all of steel, the ceiling being formed of thick steel plates. Above all is an engine and truck roadway, which is on a level with the main line, and connected with it by a new iron bridge over the Pancras Road, one of seven, all within a very short distance of each other.

TRADE NOTE.

THE Grammar School, Abergavenny, is being warmed and ventilated by means of Shorland's patent Manchester grates and patent Manchester stoves.

A SUCCESSFUL FIRM AND INTERESTING BARGE MATCH.

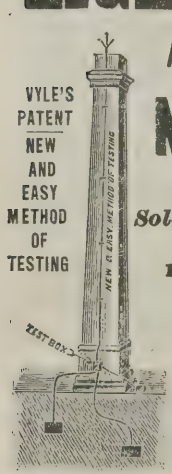
THE well-known firm of Messrs. Eastwood & Co. invited a large number of their friends to witness a race for prizes between twelve of their sailing-barges on Tuesday last (June 28). A special train from London took down to Gravesend about 200 guests, who embarked at 10.15 on the General Steam Navigation Company's s.s. *Oriole*. The start was made immediately on the arrival of the steamer on the course, and it was most interesting to watch the promptitude with which the whole of the barges got immediately under way. The smallest of them, the *Dipper*, Captain Beadle, took the lead, and held it for more than half the course of about 25 miles, when she was gradually overhauled and passed by the *Iota* (Captain Howard), who finally won after a very close race, the *Lapwing* (Captain Wheatley) coming in third. Refreshments were plentifully provided on board the *Oriole* from 10.20 to 11 A.M., luncheon 1.30 to 3.30, and afternoon tea from 4.30 till 6, when the company returned by special train to London. The luncheon was presided over by Mr. Wragge, chairman of the company, who was indefatigable in his exertions to promote the pleasure of the party throughout the day. It may interest our readers to learn that Messrs. Eastwood are the owners of not less than forty large sailing barges, mostly built by themselves, and have upwards of fifty others constantly in their employ. When the business was formed into a private limited company 1872 it owned only two barges. It had at that time only two wharves, it has now seventeen. It had no brickfields, it has now eight, from which the output in 1897 was upwards of 100,000,000 bricks. During the same period the firm supplied 30,000 tons of cement and 17,000 tons of lime. For the purposes of their London trade alone they employ 120 horses per day. At the last Whit Monday parade of cart horses at Regent's Park, the company sent twenty-two horses (nineteen entries) and took ten first prizes and six second prizes, and also in addition two special prizes for Suffolk horses.

We believe that a great deal of the success of this firm arises from the strong feeling of *esprit de corps* exhibited by all their employés.

The firm are at present occupying temporary offices at 61 Temple Chambers, E.C. They have been compelled to rebuild and greatly enlarge their premises at Belvedere Road, Lambeth. The work is now being carried out by Messrs. Perry & Co., of Bow, from the designs of Mr. E. T. Hall, F.R.I.B.A., architect, of 56 Moorgate Street, E.C.

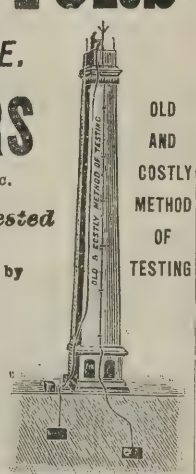
THE SANITARY INSTITUTE.

THE preliminary programme of the sixteenth congress of the Sanitary Institute, to be held in Birmingham from September 27 to October 1, has now been issued. The president of the congress is Sir Joseph Fayrer, Bart., K.C.S.I., &c.



Dr. Christopher Child will deliver the lecture to the congress, and Dr. Alex. Hill, master of Downing College, and vice-chancellor of Cambridge University, will deliver the popular lecture.

Excursions to places of interest in connection with sanitation will be arranged for those attending the congress. A conversazione will be given by the Right Hon. the Lord Mayor (Councillor C. G. Beale), and a garden party, at the Botanical Gardens, Edgbaston, will be given by members of the sanitary committee.



It appears from the programme that over 300 authorities, including several county councils, have already appointed delegates to the congress, and as there are also over 2,000 members and associates in the Institute, there will probably be a large attendance in addition to the local members of the congress.

In connection with the congress, a health exhibition of apparatus and appliances relating to health and domestic use

will be held as a practical illustration of the application and carrying out of the principles and methods discussed at the meetings, which not only serves this purpose, but also an important one in diffusing sanitary knowledge among a large class who do not attend the other meetings of the congress.

The congress will include three general addresses and lectures. Three sections, meeting for two days each, dealing with (1) Sanitary Science and Preventive Medicine, presided over by Alfred Hill, M.D., F.R.S. (Edin.), F.I.C., M.O.H., Birmingham; (2) Engineering and Architecture, presided over by W. Henman, F.R.I.B.A.; (3) Physics, Chemistry and Biology, presided over by G. Sims Woodhead, M.D., F.R.C.P., F.R.S. (Edin.). Five special conferences—Municipal Representatives, presided over by Ald. W. Cook, chairman of the health committee, Birmingham City Council; Medical Officers of Health, presided over by John C. McVail, M.D., D.P.H., F.R.S. (Edin.); Municipal and County Engineers, presided over by T. de Courcy Meade, M.Inst.C.E.; Sanitary Inspectors, presided over by W. W. West, chief sanitary inspector, Walthamstow; Domestic Hygiene, presided over by Mrs. C. G. Beale (the Lady Mayoress).

The local arrangements are in the hands of an influential local committee, presided over by the Right Hon. the Lord Mayor of Birmingham, with Prof. A. Bostock Hill, M.D., D.P.H., W. Bayley Marshall, M.Inst.C.E., J. E. Willcox, Assoc.M.Inst.C.E., as honorary secretaries.

THE VALUE OF CITY LAND.

AT the London Sheriff's Court, before Mr. Deputy Under-Sheriff Burchell and a special jury, an important claim for compensation under the Tower Bridge approach scheme came on for hearing last week. The parties to the action were Mr. West, a private gentleman, and the London County Council, and the sum involved was about 13,000*l.* According to counsel's opening statement it appeared that the Council were anxious to complete the scheme of improvement for opening up the approaches to the Tower Bridge. On the corner of Queen Street and Royal Mint Street stood a plot of land, and it was sought to acquire this. Counsel pointed out that the value of land in this part had enormously increased of late years, and, although the Council sought to depreciate the value of the land, he would prove by expert evidence that the value was much greater than appeared at first sight, and that it ranged from 2*l.* to 3*l.* per foot. Sir J. Whittaker Ellis and Mr. Edward Tewson gave expert evidence, and valued the land at 13,666*l.*, or 2*l.* per foot, with the usual compensation. For the Council expert evidence was called, placing the value at a much lower figure, and in the end the jury awarded 11,026*l.* as compensation for the compulsory purchase.

BRIGHTON AND HOVE SEWERS.

ON Monday last a select committee of the House of Commons considered the Bill for confirming a number of provisional orders made by the Local Government Board. One order, which was allowed to pass without opposition, was for altering the local Acts under which the Brighton Intercepting and Outfall Sewers Board, consisting of members elected by the Corporation of Brighton and the Urban District Council of Hove respectively, were empowered to make and maintain sewers and works, and to borrow for those purposes such sums as they might think fit, not exceeding in the whole 127,500*l.* In consideration of the fact that it is necessary that groynes and other sea-defence works should be constructed for the protection of the sewers in question, the order of the Local Government Board sets forth that the Sewers Board may construct and maintain such groynes and other sea-defence works as may be necessary, subject to the previous consent of the Board of Trade. One of the conditions is that "if any such work be commenced or completed contrary to the provisions of this order, the Board of Trade may abate and remove the same and restore the site thereof to its former condition at the cost and charge of the Sewers Board, and the amount of such costs and charges shall be a debt due from the Sewers Board to the Crown, and shall be recoverable as a Crown debt or summarily. Provided also that nothing contained in the order shall authorise the Sewers Board to take, use, or in any manner interfere with any portion of the shore or bed of the sea, or any river, channel, creek, bay or estuary, or any right in respect thereof belonging to the Queen's most excellent Majesty in right of her Crown and under the management of the Board of Trade without the previous consent in writing of the Board of Trade." Article II. empowers the Sewers Board to exercise, subject to the sanction of the Local Government Board, any unexhausted borrowing

PATENT

VULCANITE ROOFING.

Since the introduction of the patent Vulcanite Roofing into this country it has been adopted by a great number of leading architects for Public and Private Buildings, Hotels, Schools, Hospitals, Theatres, Mills, Warehouses, Breweries, Shops, Villas, Dwelling-houses, &c.

The temperature of the rooms immediately beneath the roof is more even in winter and summer than under any other roof. When properly laid repairs are never required, and all roofs are guaranteed. The roof-surface can be used as a garden, or for any other purpose. The cost of construction is less than even for a slate or tiled roof.

SHEET ASPHALTE for DAMP-COURSE, WATERPROOFING VAULTS, BRIDGES, TUNNELS, &c., is manufactured ready for use in lengths of 40 feet, and any width up to 40 inches, being more convenient than the usual damp-course slabs, and saving laps. Price lower and quality much superior to any similar article in the market.

SHEET ASPHALTE for ROOFING SHEDS, LIGHT BUILDINGS, &c., and for SARKING under slates or tiles, manufactured in five different qualities and in rolls of 15 superficial yards. It is easily laid, very inexpensive, much superior to felt roofing, and requires no annual coating.

Full particulars, Catalogues, Detail Sketches, Estimates, re Vulcanite Roofing; Samples, Prices, &c. re Sheet Asphalte, free.

Agents wanted in all districts where not yet represented for laying of Vulcanite Roofs and Sale of Sheet Asphalte.

power, and Article III. authorises the raising of a sum not exceeding 7,000*l.* in addition to the 127,500*l.* authorised by the original local Acts to be borrowed. The money so raised is to be repaid within a period not exceeding fifty years, either by equal annual instalments of principal and interest combined, or by means of a sinking fund, "or partly by one of these methods, and partly by another or the others of them." If the Sewers Board desire to accelerate the repayment of any loan they may increase the amounts payable to the sinking fund, or, if the latter should assume proportions more than sufficient, may reduce the said payments. There are many subsidiary and qualifying clauses, but those quoted embody the general outlines of the scheme. The Bill will next go before the House of Lords.

ART WALL-PAPERS.

MURAL decoration—by which not too exact term is meant the decoration of the walls of a room—has not of course escaped the influences of modern art teaching. Not only have new materials for mural application been manufactured, but the paper-stainer's art and mystery has advanced in a most astonishingly rapid manner till now, if a room—whether it be one of the perfumed chambers of the great or the modest living room of the artisan—be not decorated artistically and appropriately the fault most certainly does not lie with the paper-stainer.

A visit to the showrooms of Messrs. Charles Knowles & Co., at 164 King's Road, S.W., would promptly dissipate any doubt on this point, for at these showrooms are to be seen some of the most beautiful wall-papers which it would be possible to produce. We paid a visit to Messrs. Knowles the other day, and of some of the most striking designs in wall-papers which we then saw we now propose to briefly speak.

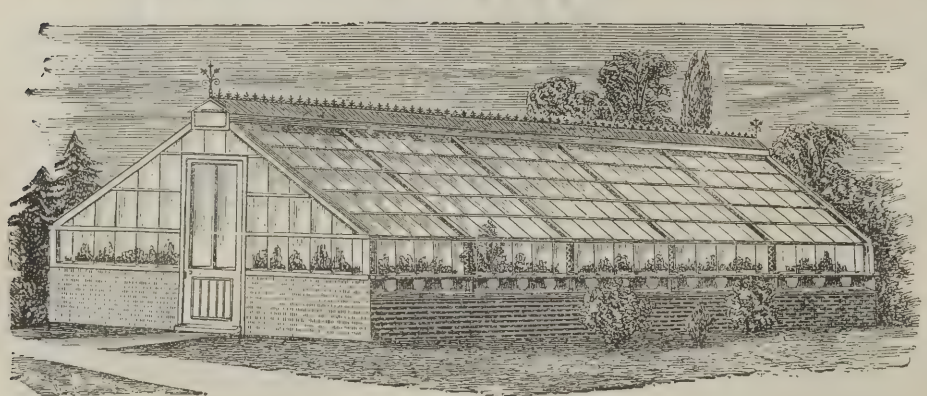
First our attention was caught by a large pattern in which poppies are very effectively introduced, the colours being natural and therefore brilliant. This paper would be specially suitable for a staircase or corridor. Its reference number is 78,025. Then there is a beautiful scarlet satin paper, No. 8,264. The colouring is very rich and deep, and the pattern full and effective. In a large room furnished in dark oak or ebonised wood this paper would have a fine effect. There is also a handsome flock paper in crimson, No. 79,425, to which attention may be directed.

An embossed paper in dark yellow and gold, No. 8,196, is also noteworthy. The design is of a floral and foliaceous character, and the treatment free and effective. There is a design in which baskets, flowers and ribbons are intertwined in a very artistic manner. It is in several colours, but we saw it in a delicate blue and applied to a panel, for which purpose in a drawing-room it would seem to be very appropriate.

Messrs. Knowles have some very fine papers in silk flock. One in orange and gold, No. 78,430, is especially so, while another in a light blue, No. 79,433, with a very delicate striped pattern in white would, in a high and well-lighted drawing-room, be peculiarly effective. There is also a flock paper, No. 79,430, which would lend itself admirably to a dining-room in dark walnut.

Ceiling papers in high relief are now a good deal employed, and in these Messrs. Knowles have some effective designs. One of a rectilinear character, No. 79,077, drab on green, and another, No. 79,071, of a more florid nature, in which circles and wreaths play an important part, would be specially worth attention, as, being heavily flocked, the relief is very high. Dado papers are not greatly in demand at the moment, yet Messrs. Knowles produce some effective designs therein, while their friezes are especially good, the designers having evidently borne in mind—it it only too frequently forgotten—that as a frieze is farther from the eye than any other part of the room's ornamentation, so the design should be bold and freely treated.

In concluding this brief notice of a very interesting visit, we must not omit to mention a pattern in which birds of paradise are introduced with good effect; an old-fashioned chintz pattern, very striking and clear; and a paper, No. 9,381, in which the imitation of the finest tapestry work is extraordinarily good. It is indeed not so much an imitation as an illusion.



THE NEW UNIVERSITY COLLEGE HOSPITAL.

THE Prince of Wales, who was accompanied by the Princess, visited the University College Hospital for the purpose of laying the foundation-stone of the new building which is being erected at the cost of Sir John Blundell Maple. The ceremony, which was excellently arranged, was witnessed by a numerous and fashionable company, and was in every respect eminently successful.

The site of the hospital is the quadrilateral area bounded by Gower Street, Grafton Street, Huntley Street and University

Street, and measures about 232 feet by 225 feet. The plan of the building is a diagonal cross, that form—which was a development by the architect, Mr. Waterhouse, R.A., of a suggestion made to him by Mr. Newton H. Nixon, the secretary of the hospital—being the best formation by which to obtain on this site the maximum of light, air and accommodation. The style of architecture adopted is a free treatment of Renaissance, and the material is red brick with terra-cotta dressings.

The half-basement, which rises 6 feet above the ground, occupies the whole of the site, and the cross-form of plan is only assumed in its entirety above the level of the first-floor. The administrative rooms and out-patient departments, together with a complete system of medicinal baths, are placed in the half-basement, which is 15 feet high, built throughout of glazed bricks and well lighted by skylights as well as windows. Access to these rooms is obtained by an inclined way, in addition to several staircases and a special lift for the use of out-patients. The wards are placed in three of the arms of the cross, while the fourth arm, that to the south, provides accommodation for the resident officers, nurses and domestic staff. At the convergence of the limbs is a central block, which contains the main staircase, two lifts, the board-room with offices and three operating theatres. The latter have large windows looking into the open space between the south and west wings, as well as a sloping top light, and at the sides of the theatres are rooms where all preparations for operations are carried out. Special attention is given in this respect to the requirements of modern surgery.

The walls of the building generally are 70 feet above the ground, and the tower in the central block rises to a height of 140 feet.

Each ward wing contains four large wards in as many storeys. These wards are 86 feet long, 25 feet wide and 12 feet 3 inches high, and have a transept projecting about 21 feet on each side, thus being cruciform in plan. The fireplaces are in the centre, with flues and ventilating shafts running up the whole height of the wing. Each ward will contain twenty-four beds, and the total number of beds accommodated in the hospital will be nearly 300.

The entire top floor of the west wing is devoted to a special department for the necessary clinical and microscopical investigations, including a large theatre and smaller rooms for clinical instruction.

A special feature in the hospital, introduced for the first time by Dr. Poore in his original plans for the reconstruction, and carried out in the present scheme, is the complete isolation of each ward. Thus, the arms are separate from the central block, and the only communication of the wards with the main staircase is by means of bridges with windows. The spaces between the floor of each bridge and the roof of the bridge below admit, it will be seen, of a free passage of air between the four angular spaces enclosed by the wings, thus preventing any possibility of a stagnation of air from whichever quarter the wind may be blowing. At the end of each wing there is a sanitary tower, also cut off from the wards by an open emergency staircase, giving free air-passage. The plan adopted, therefore, practically abolishes corridors and staircases in the hospital proper, as each ward is in communication on the one hand with the rest of the structure, and on the other with the sanitary offices only by bridges that can be freely ventilated.

AMALGAMATED SOCIETY OF ENGINEERS.

THE forty-seventh annual report of this Society, which has just been issued to the members, shows the effects of the recent engineers' dispute upon the principal trade union concerned therein. In his introductory remarks the general secretary (Mr. G. N. Barnes) observes that the period under review was one of great stress and trial. The lock-out of last year would yet have far-reaching consequences, and he ventured to think that many illusions on both sides had been dispelled in consequence of it. The lessons derivable from it were clear and unmistakable, and an immense impetus would be found to have been given to the widening out of industrial organisation and supervision. Already, and partly as a result of the lock-out, the federation of unions had been brought within the sphere of practical discussion, and stimulus had been given to co-operation enterprise on its productive side, whereby the forces of trade unionism and co-operation were being brought together. In the larger sphere of collective supervision there could be no doubt but that the impression made upon the public mind by the suffering, loss and dislocation consequent upon the lock-out would yet find due expression. True, the intervention of the Board of Trade last year was denounced by Sir Henry Howorth as an impertinence, and by the *Times* as an unnecessary interference, but reforms generally came in this way. They were denounced by reactionary newspapers and by politicians,

the latter often enough said to be men of science, until the public mind was familiarised therewith, and by others enlightened thereon. For his part, he believed that the rights and duties of the community in this matter involved the sifting and adjudicating upon the facts, and he believed this principle was bound to be accepted here as soon as it was as well understood as in New Zealand. The general secretary next deals with labour legislation during the year, his chief reference being to the Workmen's Compensation Act. "It must be admitted," he remarks, "that the new Act is satisfactory as marking a growing sense of responsibility on the part of the community. We hope it may be followed by the adoption of a more complete system of safeguards, so as to minimise risk in unhealthy trades." Turning to the figures appertaining directly to the operations of the Society, they had 87,455 members at the commencement and 91,444 at the close of the year, an increase of 4,589. The income was 559,368*l.*, which, added to balance from 1896, amounted to 865,251*l.* The expenditure was 690,399*l.*, leaving a balance of 174,852*l.* at the close of 1897. From this must be deducted 20,000*l.* excess of moneys borrowed over those lent, so that the real total assets in December last amounted to about 154,000*l.* This would come as somewhat of a revelation to many who at the time in question were indulging in pessimistic twaddle about the effacement of the Society, and especially so to the journalistic Jeremiahs who argued from the capitulation of January last the utter rout and demoralisation of trade unionism as a force in industrial progress. With regard to the income, contributions from members amounted to 448,936*l.*, or about 25 per cent. above the highest previous total, and voluntary contributions to 77,765*l.* On the expenditure side donation and contingent disbursements amounted to 281,177*l.* and 129,077*l.* respectively. Under the heading of emergency fund and local levy grants was the amount of 113,677*l.*, or a total under the four headings of 523,932*l.*, and deducting 100,000*l.* as representing normal expenditure, the remainder was cost consequent on the lock-out. Sick benefit had been reduced from 44,667*l.* to 42,407*l.*; superannuation benefit had increased from 63,747*l.* to 68,760*l.* Funerals had cost 12,735*l.* as against 12,799*l.*, and benevolent grants 2,134*l.* as against 2,663*l.* in the previous year. Cost of management amounted to 35,670*l.*, equal to 7*s.* 9*d.* per member, or 1¾*d.* per week.

In conclusion, Mr. Barnes remarks that the past year had been the most momentous in the Society's history. It had been a year in which the fidelity of the members had been put to a severe test, and they had not been found wanting. They had suffered a severe reverse, it was true, and spent a great deal of money, but such reverse came in a justifiable and well-sustained effort to make the conditions of London life more tolerable for labour. They believed the abridgment of the working day for which the Society struggled was not lost, but only deferred for a time. Finally, they were convinced the cause of labour would be advanced by what had taken place.

PATENTS.

AT the monthly meeting of the Campbelltown (N.B.) Town Council on the 22nd ult. it was agreed to proceed with the enlarging of the council chambers at a cost not exceeding 150*l.* Mr. M'Murchy called attention to the inadequacy of the town hall for public entertainments and meetings, and suggested some improvements, including the erection of a back gallery.

THE NEW EXPANDED METAL

Meshes from ⅛th in. to 6 in. wide. Strands from 24 B.W.G. to 3/16th in. thickness of steel.

FOR BUILDING CONSTRUCTION, as supplied to a large number of important Buildings, both Public and Private, in this country and abroad.

FOR SOLID PLASTER PARTITIONS, 2 inches thick, with Expanded Metal Lathing. Fireproof, vermin-proof and practically sound-proof.

FOR FIREPROOF LATHING, for attaching to wooden joists and studs, for walls and ceilings, also for suspended ceilings, ornamental mouldings, encasing columns, girders, &c.—no cracking or falling away of plaster to be feared.

FOR CONCRETE FLOORS WITH EXPANDED METAL.—The remarkable results and advantages of these will be better understood by perusal of the Report hereinafter referred to.

FOR EXTERIOR WALLS OF BUILDINGS.—Cement applied to Expanded Metal is not liable to crack or fall away through changes of temperature.

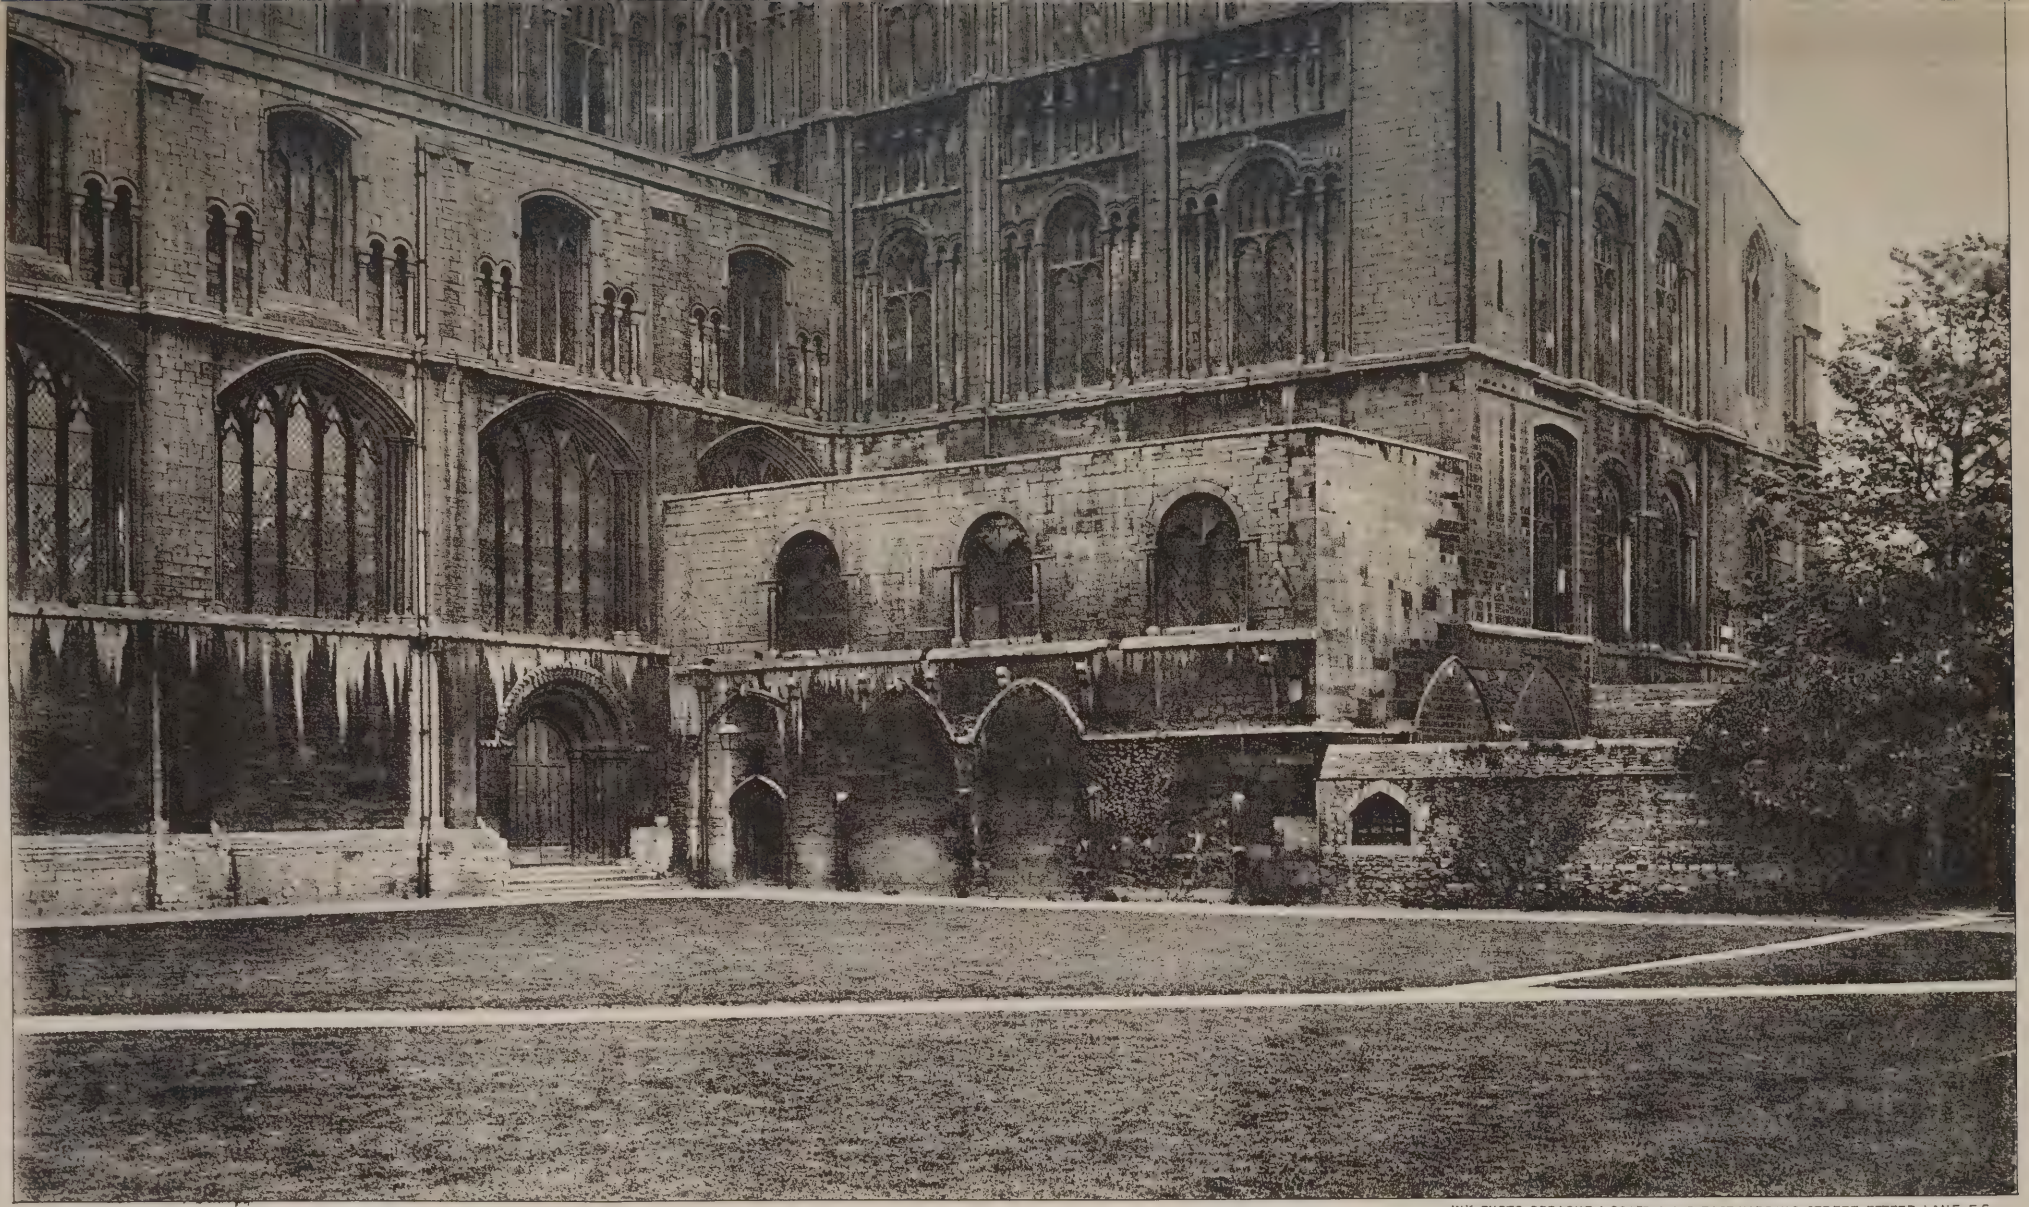
FOR FENCING, TREE GUARDS, WINDOW GUARDS, as supplied to the Royal Parks, leading Railway Companies and landed Estates throughout the Kingdom.

ORNAMENTAL. STRONG. CHEAP.

OTHER USES FOR EXPANDED METAL.—These are innumerable. It can be used wherever lattice-work is required, from a letter-rack to a lift-shaft, for garden bordering and archways. Is highly ornamental and exceedingly durable, having no joints to rust away.

Being expanded by rapid machinery it is considerably cheaper, strength for strength, than any other description of metal lattice-work.

BRASS, ALUMINIUM, or any other ductile metal can be expanded, and the effect is very pleasing, and here again the absence of joints gives great durability to the metal, and the rapidity of manufacture allows of very low prices.



CATALOGUES AND PRICE LISTS can be obtained on application. Also copy of a REPORT by an EMINENT FIRM of ENGINEERS on the use of EXPANDED METAL IN CONCRETE.

SIR A. W. BLOMFIELD, Architect

The Architect.

THE WEEK.

The building known as Abbey Mansions, in Orchard Street, Westminster, seems destined to exhibit all the shortcomings of building law as well as of one variety of building practice. On Tuesday the supposed owners were summoned under the dangerous structure clauses of the Building Act and also for the following breaches of the Act:—(1) Erection to a greater height than 80 feet without the consent of the London County Council; (2) that the roof storey (more than 60 feet above the street) was not constructed throughout of fire-resisting materials. Mr. Avory, for the defendants, maintained that the building did not come under the general enactments, as it was a Government building. According to Clause 202 of the Act of 1894, "Any building, structure or work vested in and in the occupation of any department of Her Majesty's Government for public purposes or for the public service" is exempted from so much of the provisions of the Act as relates to structures and buildings. The coroner, at the inquest, considered the exemption did not apply, because the Office of Works, although lessees, had not entered into occupation; and apparently on his suggestion proceedings were taken by the County Council. Counsel said he could not understand how a building could be occupied when it was not completed. The magistrate considered that, by the agreement, the premises were vested in the Government, and must therefore be considered as exempted. But he adjourned some of the summonses in order to see whether a case would be applied for. The litigation has hardly commenced, but we are afraid many other legal fiascos will have to be recorded in connection with the case. That would be unfortunate, but the consequences will be more deplorable if people become persuaded about the possibility of defeating justice by an excess of carelessness in building operations.

The prospective value of an architect's plans may be indefinite and therefore difficult to calculate; but as they often have their use as legal documents and can enable the possessor to save time and labour in preparing plans for other buildings, they become contingents which deserve appreciation. There is, however, no actuary or valuer for probate who would be able to afford data for determining how much in standard coin the plans of an ordinary building are worth to the designer or his successor if he sold his practice. That a case in which the problem has to be raised can come before the Courts is plain from a report in the *American Architect*:—A certain architect went off on a fishing trip, leaving his rent unpaid. His landlord, in his absence, seized his office furniture and his plans, the accumulation of twelve years of practice. Before the account was settled the plans had been lost, or, as was supposed, destroyed, and the architect sued his landlord for their value, which he set at 25,000 dols. Several architects were called as expert witnesses to testify to the value of the plans, but their evidence was so unsatisfactory that the plaintiff is said to have abandoned his case. The counsel for the defendant insisted that the witnesses should estimate in dollars and cents the value of the lost property, and, as in the case of so many other conscientious witnesses, they were hopelessly confused by this ancient legal trick. If the case were tried in London instead of Chicago, would the issue be different?

The County Council have decided to apply to Parliament for powers to construct a new street from the Strand to Holborn, a scheme which we have already described. It is proposed, also, to form a subway beneath it and to plant trees. The principle of betterment will be applied on similar conditions to those adopted for the Tower Bridge approach (south side), but a longer period than three years will be sought for judging of the effect of the improvement on the surrounding property. Provision is to be made as far as possible for rehousing the people displaced previously to giving up their rooms, and no one is to be transferred beyond a mile. The improvement could not be delayed much longer. But probably the cost of so important a work will not fall more heavily than is anticipated on the inhabitants, although, as we have already pointed out, the expenses of construction are estimated on an economical scale. The rehousing is no light task, and it is hardly to be realised from the amount to be expended, viz. 300,000*l.*—the largest sum expended on work of the kind.

Visitors to the exhibition of French pictures at the Guildhall cannot forget the sinister figure of the Capuchin monk in M. Gérôme's *L'Eminence Grise*. The Père Joseph le Clerc de Tremblay was a more important associate of Cardinal Richelieu than he appears in Lord Lytton's drama. It is strange there is no portrait of so mysterious a personage in any of the public collections of France. M. Rossigneux, who was formerly Prince Napoleon's architect, possesses one which was apparently painted by a brother of Simon Vouet. It is therefore valuable from its interest as an example of the portraiture of the early part of the seventeenth century. It was offered to the authorities, but they have declined to accept the gift of M. Rossigneux. Can the rejection be due to political causes?

The proposed establishment of a university in Birmingham must excite the attention of all educationalists. Universities are not founded every day, and in Birmingham it is intended to depart from precedents. Strictly speaking, a university is intended to teach the humanities, and the question which will have to be considered will turn to a great extent on whether Greek and Latin are to give way to modern languages, and whether literature is to be supplanted by science. The old universities were adapted to the circumstances of the time when they came forth, and why should not Birmingham also have a twentieth-century system of education? Competition in industrialism has become so intensified that Birmingham has to fight for existence against many rivals. The promoters of the project should be pardoned if they conclude that metallurgy is of more importance than speculations about Vulcan's shield or the decorations of the palace of King Alcinous. But we hope science will not alone be taught. In everything formed of metal which Birmingham is likely to produce art is required. For industrial art the classes in the municipal school of art, excellent as they are, are not sufficient. An academy of art should form a part of the university in which architecture will be recognised as it deserves, for the failure of the Slade professorships suggests that amateurish discourses are not adapted to the needs of Birmingham.

The Royal baths in Stafford were erected six years ago, and in the annual abstract of accounts just issued the sum of 313*l.* is entered for alterations and repairs. The amount is not exceptional. It seems incredible that so large an annual outlay should be needed, and it is no wonder that, while the income was 782*l.*, the expenditure should be 1,376*l.* A company could not long exist that conducted business in a similar way, and the subject should be inquired into by a specialist who does not live in Stafford. Fortunately compensation is to be found in other departments under the supervision of the Town Council. The gasworks have brought a profit of 785*l.* The electric lighting, with an outlay of 739*l.*, yielded a profit of 553*l.*, and from the waterworks the profit derived was 2,441*l.*

A new volume of the Amateur Photographer Library, entitled "Architectural Photography," has appeared from the practised hand of Mr. G. A. T. Middleton. It is written with his usual conscientiousness and knowledge of his subject. Although it costs only one shilling, it contains a great many illustrations. There is no attempt to write the history of architecture. What Mr. Middleton does mainly is to suggest how the most expressive photographs of buildings are obtainable. That has an advantage for photographers, whether professional or amateurs, but a great many of the suggestions can also be utilised by architectural students when on sketching tours.

THE SWISS MUSEUM, ZURICH.

BY A CORRESPONDENT.

THE world in general considers Switzerland as a small but picturesque State inhabited by people who are very prudent and industrious, and who have contrived to play an important part from time to time in European history. MACAULAY'S schoolboy if tested would be likely to remember more of the historical incidents of the Swiss than of his own countrymen. So much is made of the old records that modern sceptics appear to take delight in proving that much of what is told has no more real foundation than the "Kinder- und Hausmärchen" which also excite interest everywhere. But the Swiss themselves take an altogether different view of their rights and their history. Switzerland is to them only a geographical and political expression, which brings with it the inconvenience of performing certain services and paying certain sums which are demanded in order to keep up that federation which is to the majority no more than a necessary evil. The interest of a Swiss rarely extends beyond his own canton; in most cases it is confined to his own district. He considers, too, that the esteem in which the Swiss as a race are held is only a diffusion of the admiration which belongs to his canton or race, and what should be his is shared in by others under false pretences. Three forest cantons claim all the interest which is attached to the insurrection of WILLIAM TELL. Berne and Zurich unaided defeated ALBERT OF HAPSBURG. It was Lucerne gained the victory of Sempach. Zurich was the first to adopt the Reformation. The cantons were as disposed to fight against their neighbours as against the Austrians. Zurich at one time was besieged by a Swiss confederation. In the sixteenth century Catholics and Reformers engaged in a war over the appointment of an abbot for the Monastery of St. Gall, and there was great slaughter on both sides at the battle of Cappel. The love of liberty or the assertion of individuality among the Swiss is not without its drawbacks, and one is the existence of something which has a resemblance to what is known in England as parochialism. It seems the more strange when found in a region where so much is seen to suggest the immeasurable universe of which the mind is the reflection.

All this may appear an odd introduction to a notice of a museum which abounds in "auld nick-nackets" that would have won the heart of Captain GROSE. But the museum is more than a refuge for remains of antiquity. It is a memorial of a victory of Switzerland as a nation over the petty interests of the cantons. For years the project was advocated by a few enthusiasts who were looked on as bores of the first magnitude. It was asked what could be the advantage of an institution of the kind? The people were not indifferent to the past, and in the principal cantons museums are to be found containing local relics which, it was maintained, became more interesting the nearer they were to the places where they were produced or set up. As far as one looked back, Helvetia was made up of several distinct districts each claiming independence, and opponents inquired why should not archæology express a historical fact? The national idea, however, slowly gained in favour. When it became strong it was met by the parliamentary strategy which is as fatal to ideas of reform in Berne, Lucerne, or Zurich as in Washington. For a time it seemed as if the National Museum was to be included among the "Heimathlosen."

One difficulty arose in fixing a site. Every large town asserted a right to selection on account of its historic importance. As there appeared no possibility of a settlement, it was decided to leave the choice to foreign judges. Sir A. W. FRANKS of the British Museum, M. DARCEL of the Cluny Museum in Paris and Dr. ESSENWEIN of the Germanic Museum in Nuremberg were requested to consider the subject. They came to the conclusion that Berne was the most eligible place. Then followed a renewal of lobbying. The Bund was compelled to set aside the judges' award, and bestowed the distinction on Zurich. But distinctions are costly in Switzerland. The inhabitants of the "Swiss Athens" found that if they were to have charge of prehistoric weapons, Gothic woodwork and specimens of the halbards, axes and two-handed swords which left many a foe on the field, they must pay for the building which was to contain the treasures. The Zurich people have had to buy more than once their privileges, so they accepted the inevitable and commissioned M. GULL, the architect of the town, to prepare plans for the building. M. HENRI ANGST, the British Consul-General, was appointed director.

The museum, which is found near the railway terminus and trade school, is in style somewhat suggestive of its purpose. It would be impossible to obtain from archæologists a decision about what period is most deserving of representation in the galleries. Prehistoric, Roman, Romanesque, Mediæval, Renaissance would each have supporters who were prepared to go all lengths in support of what they specially admired. In the exterior of the building M. GULL also suggests variety, and leaves the discovery of unity, if there be any, to the spectator. The National Museum is like many a Swiss building where stone or brick is made to assume appearances which must originally have been derived from construction in wood. It is always easy to condemn a modern building by thinking of qualities which the architect never cared to express. If the building is considered fantastic by a foreigner, to the people of Zurich it is a picturesque object, and with the tower and trees a group is formed which will long delight the eyes of young and old.

Although the project of the museum was met with so much opposition, the interior suggests that the State has endeavoured to make compensation for former indifference. A great many of the objects seen are lent from private collections, but there is evidence that, in spite of its rigorous economy, the Government have expended money liberally in order to make the museum worthy of the country. As far as practicable, the casket corresponds with the contents. The rooms cannot be as varied in character as would be necessary if the possessions of the cave dwellers or those who resided in houses over lakes, the monastic furniture, the faïence, the manuscripts, and so on, were placed in environments like those in which they were originally seen. Neither the Cluny nor the Brussels museum, although both are veritable examples of ancient building, is in keeping with more than a part of the collections in each. There are in both objects which are older and others more modern. But in Zurich, wherever something was acquired of sufficient size and importance to impart character it has been employed as a sort of *motif* in designing the room which was to contain it. As a consequence, the chilling effect caused by the character of the building, which in Bloomsbury deters so many young students from taking an interest in archæology, as if it signified reflections among tombs, will be absent from the Zurich museum. It will be impressed on the visitor from what he sees that in former days architecture was not an isolated art which could be exemplified only in buildings on a great scale, but that there was a relation between the style of a house and the majority of objects which were to be found there. As an educational institute for young archæologists, especially for those of Switzerland, we do not know of another which will have so many advantages as the Zurich museum.

Many of the objects must necessarily resemble those deposited in other museums, for in all times forms as well as ideas appeared to be common throughout Europe. But there is an abundance of local peculiarities which can give rise to speculation. The objects which belonged to the earliest inhabitants of the Schaffhausen district, or those who have left records of their existence, are proofs that those cave-dwellers were of smaller size than similar folk in our own island. The pieces from the lake dwellings are interesting; but as the lake at Zurich was selected as one of the refuges of the primitive inhabitants, and, moreover, from its importance in the history of the discovery of the pile-houses, imagination led us to expect more than we saw. But that is a common experience with visitors to new museums. The Roman period can never be fully illustrated. The disturbances must have been on an extraordinary scale. CÆSAR, who speaks of the Verbigenus, may have stood on the site of Zurich. But the civilisation of the Roman was not to the taste of the Helvetii. The invaders suffered defeat, and there was a migration into the more fertile Gaul. Then Roman discipline prevailed, and only a remnant of the Helvetii returned to their wilds.

Alternate victories and defeats followed both sides for four or five centuries, and when the northern tribes came in it would be hard to say who were the possessors they had to attack to gain the upper hand. Christianity was without power until the seventh century. We must therefore expect that the objects which belong to the pre-Mediæval period are not as numerous as would be expected in a country which the Romans coveted, and which was not remote from Italy. The most interesting are some statuettes, but, as usual, they appear to have suffered from their contact with the earth. Some examples of jewellery and household utensils are also to be seen.

The earliest Mediæval work is a room from a house in Zurich, which has been skilfully reconstructed. Terra-cotta manufacturers will be surprised with specimens of bricks, probably produced in the thirteenth century, on which patterns are impressed. Another room, which dates from 1476, shows the excellent work which was produced in Mellingen at that time. The rooms from a nunnery in Zurich are a little later, and are likely to excite much curiosity. Painted ornament was much employed at the time. Ecclesiastical work is well represented, and there are some good specimens of the stained-glass for which the Swiss were in repute.

A part of the exhibition which is sure to be attractive is the hall devoted to the display of arms. It exemplifies the history of the Swiss, who in every country were compelled to fight for existence. We hope that photographs will be published of the collection, for they would be invaluable to all who have to represent arms and armour on canvas. The Swiss armourers supplied weapons for the rank and file of the armies of other countries, although there were finer varieties to be obtained elsewhere, which captains could employ. Some, like Scottish weapons, retain names which suggest their origin—as the Lucerne hammer, the Swiss pike, the Sempach halbard. Most interesting also are the early specimens of firearms. In all such collections the weapons which have a history are more sought after by sightseers than those which are only remarkable for form or ornamentation. For the people of Zurich nothing is likely to surpass in fascination the sword and helmet of Zuingli, the reformer, who was preacher in the cathedral, and by whose influence ecclesiastical property was secularised for the public benefit. He was killed at the battle of Cappel, already mentioned.

The museum likewise contains rooms which are no less suggestive of the domesticities in the Renaissance period. One recalling the Casa Pestalozzi of Chiavenna exhibits Italian treatment, and excites reflections about the respective influence of Germany, France and Italy upon Swiss art. As a whole the last was weakest. Very different is another room derived from Wiggen. Zurich has still many fine old houses, and they have been utilised to suggest the costliness of decoration in the seventeenth century. In course of time, as additions are made to the collections, the appropriateness of the setting will be more apparent. Not only is Domestic architecture exemplified, but it becomes a sort of basis for the system of arrangement which is adopted, and which should be retained hereafter. In classification of all kinds there must be a leading idea, and what strikes the visitor is that in the Zurich museum that idea was architectural.

According to some experts, there is a decline in England of the fascination which "blue and white" exercised a few years ago for the decoration of walls. But a sight of the room devoted to the Winterthur faïence is almost enough to revive an interest in "crockery" as an aid to domestic adornment. The examples testify to the skill attained in the canton of Zurich in the seventeenth century. The Winterthur variety is not much known in England, but it proves that the men, women and children who were occupied in it showed much aptness as ornamentists and potters. The difficulty of exportation was no doubt one reason why the faïence was not in request in other parts of Europe. In Zurich porcelain was preferred, and there are many pieces which are skilfully painted, although the landscapes and figure groups may appear to be old-fashioned and inappropriate. The Swiss artist, although not unwilling to accept foreign money for his productions, did not trouble himself about foreign notions of taste. He worked to please himself, and preferred subjects to which he was bound by many ties. The Zurich museum shows how stubbornly certain principles of art were held from generation to generation, although with all the perseverance the nearest approach to a Swiss style is to be discerned in the woodwork alone.

Many English people will visit Switzerland this year, and we recommend them to arrange their tours so as to include Zurich. The town itself may be familiar to them, but in the new museum they will see many things which are novel, and, if rightly considered, will enable them to derive more interest from the cantonal museums.

PANAENUS THE PAINTER.

ONE of the obstacles to the study of ancient art, and it might be said of ancient life in general, is that we persist in assuming that modern practice must be taken as the standard. Accordingly, whatever is supposed to correspond with things that are familiar to us is considered supreme. This is especially the case in the history of the arts. Among the Greek painters, for example, Apelles and Polygnotus are the first names which arise in our thoughts whenever we think of the art followed by them. The reason is that from all the legends concerning them we imagine they were not unlike some of our academicians. Lord Beaconsfield, when referring to his own portrait, spoke of Millais as Apelles. That might be considered an exaggerated compliment by those who identify the Greek artist with such works as the *Venus Anadyomene* and other figures of the goddess. But it should be remembered that Apelles was also renowned for his paintings of historic characters, and his *Alexander the Great*, who was represented as Zeus, the lightning-holder, was in his day almost as famous as his numerous nude figures of women. The name of Polygnotus is also remembered because he was supposed to be a wall-painter who brought that variety of art to perfection. Many people have believed that Lord Leighton was its latest representative. Both the Greek painters would have acknowledged the supremacy of architecture, and endeavoured to prove their loyalty to the art by making their work subservient to the details of the buildings they adorned. But there were many other famous painters in Greece who appear to have been still more closely associated with architecture, and on that account are too generally ignored. One of the most remarkable was Panaenus, or, as the name has been also written, Panaios, Panainos, Pantainos.

He is sometimes described as the brother of Pheidias. But by other accounts he was the cousin of the sculptor. Whatever was the exact relationship between them it would appear as if Panaenus was generally associated with Pheidias. The sculptor was willing to follow precedent and to employ wood as well as marble for figures. In such cases the aid of Panaenus was invoked to impart more animation to the carving in wood. The sculpture would therefore correspond with the work which was long afterwards found in Gothic churches, and the circumstance is important as an indication of the antiquity of polychromy in connection with the sculptor's art. Pheidias was more renowned for figures in which ivory was the principal material. Gold was also used for accessories. To what extent the ivory was painted can only be conjectured. The descriptions which have come to us will bear a variety of interpretations. It would be easy from some accounts to suppose that the *Zeus* of Pheidias in Olympia gained effect because the ivory mass stood against a coloured background in which the richest embroideries were employed, and the figure became sublime from the appearance it presented of being simply idealised human flesh. The ornaments, although of gold, would then appear to be of very inferior value. From the description of Pausanias it is evident, however, that figures were introduced on the throne which were imitations of a painter's work. They might, of course, be only monochromes, and in them a sculptor's reliefs could be imitated. But in the age of Pheidias the Greeks had advanced beyond the monochrome stage, and it is more probable the imitations of painters' work would display the primary colours at least. If that were the case we cannot suppose the ivory body of Zeus would be left in its natural

colour. It would be stained or painted wholly or partially to be in keeping with other parts of the work.

We have the authority of STRABO for the existence of numerous paintings by PANAENUS in the Temple of Zeus at Olympia which excited the traveller's wonder. We learn also from PAUSANIAS that on the wall near the enthroned deity there was a series of mythological paintings which came from the hand of PANAENUS. The pictures were considered so interesting that provision was made by means of wooden of gallery to enable visitors to study those which were on a higher level. The titles were painted near the scenes in order to make the subjects more clear. Putting all the evidence together, it appears to be conclusive that the steps, sides, or back of the throne of ZEUS were painted in some way which increased the effect of the delicate work of PHEIDIAS, and that the background was painted with representations of victories over the Persians in which all the Greeks were supposed to co-operate, and which demonstrated the favour of the monarch of Olympus. We must also conclude that PANAENUS was accepted as a painter who was able to add interest to the exquisite sculpture of PHEIDIAS. This position becomes more honourable if we bear in mind that PHEIDIAS was, according to tradition, a painter as well as a sculptor. It may be said that he directed the painting at Olympia, and that PANAENUS resembled one of the subordinate sculptors who worked on the Parthenon. On such subjects conjecture must be left to have its way. The division of labour in ancient art did not trouble the philosophers, and, as they bestowed little attention on the production of statues, pictures and buildings, it would be vain to seek after information. If we possessed accurate information about the sanctuary at Olympia, we might learn that the two artists were able to enter into emulation without any sacrifice of either art. Both sculpture and painting became testimonies to the greatness of the god and the indebtedness of the Greeks to his protection.

It is evident that PANAENUS could be more than an auxiliary, although such a relation to PHEIDIAS would be most honourable and sought after by the ablest artists of the time. His painting of the *Battle of Marathon* in the Poecile of Athens was one of the works of which the city was most proud. Whether he set the example of painting in the gallery cannot be determined, for some inquirers believe the honour belongs to POLYGNOTUS. The painting, or series of paintings, by PANAENUS could have borne no resemblance to modern battle-pieces. The latter are supposed to be most successful when they suggest the collision of indistinguishable masses of men and horses, amidst which a few figures have sufficient definiteness to suggest passion as well as scale. But any tumultuous effect was not in keeping with the spirit of Greek art, and, moreover, the painters were unable to treat figures on several planes. In the *Battle of Marathon* there was apparently as much regularity as would be found in a sculptor's frieze. There was no need for the painter to exercise his imagination. Many of the Athenians who took part in the battle were still living, for it was not more remote from PANAENUS than the Charge of Balaclava is from painters of our time. Some of the heroes served as models to the painter, for those who were dead portraits of various sorts were used. We know that PHEIDIAS committed an offence by allowing a portrait of himself to appear among the groups of the Parthenon; but in a work like the *Battle of Marathon*, for which it was possible to be veracious, portraiture was rightly employed. The painting was a memorial of warriors who were known, and to keep up its character the name was inscribed under or near each figure. Warriors who were introduced would naturally demand to be represented as performing the deeds of which they were most proud, and when all the restrictions are taken into account we cannot suppose that the Greek battle-piece consisted of more than a series of conflicts of an Athenian versus an invader, in the style of the contests between the Lapiths and the Centaurs which filled the metopes of the Parthenon. There was some analogy between the two scenes, for as the Persians were represented as far bigger men than the Athenians, the contest became one of brute force against courage inspired by intelligence. The groups were not necessarily separated by blank spaces. By arranging them in bands or friezes the chronological order of the incidents, and the beginning, middle and termination of the struggle against the invaders would be suggested. An important part of the picture represented the panic of the Persians, who became their own enemies. But as the Greeks could always make a part serve for the whole, there was no need to depict the scene as it would be done by one of the modern war correspondents who use the pencil.

There could not fail to be marked limitations in the pictures of PANAENUS. Arms and men were his subjects. The Greeks for whom he painted did not appreciate women in paintings unless they appeared as Amazons, and the value of costume as an adjunct was not demonstrated. Domestic scenes would be considered ridiculous, landscapes evidence of lunacy. Painting corresponded with the architecture, and the sculpture. It attempted to be heroic, and, as we have seen in the case of PANAENUS, the glory of a man who followed that branch of art was to enable architects and sculptors to realise effects which otherwise would be impossible.

A BIRMINGHAM UNIVERSITY.

A MEETING was held in the Council Chamber, Birmingham, on the 1st inst., for the purpose of making arrangements for the establishment of a university in the city. The Lord Mayor presided.

Mr. C. H. Kenrick moved the first resolution which was as follows :—"That in the opinion of this meeting it is essential that in the interests of the city, and the Midland district generally, a university shall forthwith be established in Birmingham." In the course of his speech Mr. Kenrick said he found some of his friends saying they knew quite well that their industries were dependent on science, but they did not want to have people around them knowing too much about it. When the time came, they said, that they required the scientific man, they would send for him, and no doubt he would give them all the information that was necessary. He ventured to think that was a sad delusion. A man of science called in on those occasions, although he might be able to prescribe for every other defect and ailment, was, he thought, always unable to prescribe the exact remedy for the particular disease respecting which he was called in. It was not to be wondered at. Industries had done nothing to enlighten those interested in science, and they could not be surprised if scientific men did not quite understand all the industries. There had been too much thought for the individual, too little thought for the industry. They required to learn something of the co-operation of trades for the purpose of their advancement, and for the purpose of reaping the full benefit of the scientific discoveries of the last twenty or thirty years.

Professor Tilden, in seconding the motion, said that though he had the misfortune to be a professor he was disposed to go even farther than Mr. Kenrick did in regard to the functions of a university. It might be asked what was the use of a university in a great manufacturing district like that? The public idea of a university was based chiefly on the notion that it was a place at which people got degrees, and few who had not had university experience had an accurate conception of the nature of the process by which those degrees were obtained. There had been a prejudice to a certain extent in the minds of commercial men against a university training, because they had been rather disposed to think it a sort of thing that was all very well for schoolmasters and clergymen—it had not any practical bearing. But a university rightly organised and rightly conducted might be the most practical thing in the world. They heard almost daily statements concerning the wonderful advances that had been made in industrial progress by Germany during the last few years. They were all agreed that Germany had made great progress, and that the Germans were an eminently practical people. In the German Empire there were twenty-one universities with an annual income of about 1,250,000*l.*, of which about three-fourths was contributed by the State. The Americans, too, had the character of being a very practical nation, with a strong inclination to take advantage of inventions which led to convenience in life, to saving of labour, to saving of time, to saving of money. Now, in the United States there were several hundred institutions which claimed to be universities. Of course he would not refer to those very numerous thriving institutions which merely assumed the name without any right, but he could point to some seven or eight very eminent universities in the United States, universities which, though perhaps half a century ago they were comparatively poor and possessed of comparatively feeble resources, had now become institutions of the utmost national importance. The annual income of Harvard was now 260,000*l.* per annum, that of Cornell 105,000*l.*, and that of Baltimore, the celebrated John Hopkins University, 35,000*l.*

France since the war had been stirred into great scientific activity. There were distributed through many of the French towns faculties of the University of France, with incomes varying from about 12,000*l.* to 40,000*l.* a year, and the magnificent building of the Sorbonne in Paris, in which the Faculty of Science was housed, showed how much scientific activity of an educational kind had now been aroused among the French people, no doubt partly by the example of their neighbours across the Rhine. He scarcely need speak of Switzerland. They had heard of the university and the great technical school at Zurich—an example of the most wonderful foresight and the most wonderful liberality of spirit displayed by a comparatively small and poor country. Now, these universities were not places that had been founded in order to satisfy the sentimentalist or the mere visionary. They were places which had a practical share in the life and had a very important influence on the industrial position of the several nations he had referred to. Dr. Ehrhardt, whose letter had been read, and whom he (Dr. Tilden) had the advantage of instructing in science in his early years, was one of the leaders in a big factory in Germany, the Badische Soda und Anilin Fabrik, which manufactured not only dyes, but sulphuric acid and soda, which were the two fundamental things in chemical industry. The factory employed 5,000 men; its capital was 18,000,000 marks, and its working capital about double; the market price of the shares was 454 per 100; it had paid recently dividends of 24 and 26 per cent., and had not paid less than 20 per cent. since 1890. That great industrial concern was conducted by a board of directors and a staff of managers and foremen, 110 in number, nearly all of whom were graduates holding their doctorates from the universities of Germany. Chemistry, of course, was not the only department of science immediately beneficial to industry. In iron and steel works not only metallurgy, but engineering came in, the successful manufacturer depending not merely upon chemical processes, but to a very considerable degree upon engineering skill. Then there were the very rapidly increasing applications of electricity, not only for lighting and for driving machinery, but as displacing some of the other chemical and metallurgical industries. All these things demanded the highest kind of scientific knowledge. The polytechnics of London and the municipal technical schools in the provinces had done good service, but these institutions were inferior to the polytechnics of the Continent in that they only gave partial instruction to persons who were occupied at business, and in that the scientific standard of the staff in most of these institutions was not to be mentioned in comparison with the staffs associated with the great polytechnics of Germany, in which many of the teachers of chemistry, or electricity, or engineering were people of world-wide reputation in science. The German manufacturer believed in science and in training the intelligence, and made use, if at all, only to a small extent of what was called rule of thumb. Then the German universities gave degrees under conditions wholly different from those which prevailed in nearly all British universities. A man who had graduated in a German university was not merely a cultivated man, but he had learnt a branch of science so thoroughly and in such a practical way that he was able on leaving the university to turn his scientific knowledge to practical account for some industrial purpose, his case being in some degree analogous to the case of a doctor of medicine in this country. If we wanted our university degrees to inspire confidence on the part of the manufacturers, as did the degrees granted abroad, we should have to alter the conditions under which degrees were now granted. The ancient universities were no doubt alive to a part of this question, but they were hampered in various ways, partly by want of funds—for both Oxford and Cambridge were in a very impecunious condition. At Cambridge a very interesting experiment—the engineering laboratory and the mechanics' tripos—had been tried, and it was possible there for a man to take a degree in practical mechanical engineering. At Glasgow and at Edinburgh the universities had engineering schools, and in connection with the Victoria University there was some engineering teaching. But in Birmingham they were their own masters, and they had a great opportunity of creating a university of an entirely new type, a place for study and also eminently a place for research, and a place where he hoped they would get rid of that predominance of examinations which unfortunately prevailed in most of the other British universities. They must have examinations to prove that the students had availed themselves of the system of training and instruction, but for practical purposes examinations, in the ordinary sense, could never be a true test, simply because they could not be carried on long enough. In a properly constituted university the student would be under examination by his professors from the moment he entered until the time he received his diploma. Then Birmingham might inaugurate, as he suggested some ten years ago, a faculty of technics or applied science, in which should be put on an equality, as far as honours and rewards were concerned, all subjects which were related to the application of science to industry. With possibilities such as these in view, he thought the movement they were inaugurating that day ought to secure the sympathy and support of all the inhabitants of that great industrial region.

Mr. Chamberlain, M.P. (Colonial Secretary), also addressed the meeting, and in concluding his speech said:—You know, gentlemen, what a great change has taken place in the course of the last few years in our methods of business. Trades and industries which formerly were in the hands of private firms—whose members never, I think, were wanting in recognising their obligations to the community in which they lived—have now been turned over in many cases to boards of directors and shareholders. It always seems to me as if the first thing that these limited companies wanted to limit was their liability to the general public. That, I hope, will not be the case in regard to our present enterprise. If it is to be the case, I think the time will come shortly when it will be impossible to carry out any philanthropic or public work in our great towns. If it is the case, I venture to utter my warning, and to say that it will destroy that sympathy between classes, that community of interest, which has done so much in the past for this country; that, in place of it, you will find indifference on the one side, followed by suspicion and distrust on the other, and you will be encouraging, if you do not justify, those extreme Socialistic views which have done so much harm on the Continent—harm to the general prosperity of the nation and to the welfare of the working classes. An appeal, an organised appeal, will be made to the great companies which are carrying on business in Birmingham, and I venture to hope—I will say more, I believe—they will respond at least as liberally as would have the private individuals whom they have replaced. The second point is this. There is no doubt that our public life owes a great deal to the liberality of those ancient guilds and corporations by which the trades were controlled, and which have now almost disappeared, although I think that there are signs that they may be revived again on modern principles and in modern guise. But, however that may be, I think it is most desirable that the individual trades of Birmingham should be identified from the first with the new university, and I venture to hope that where the particular business is not large enough to justify on the part of the proprietors any very large subscription, they may nevertheless be associated as a trade, and in that way, by a multiplicity of small subscriptions, may reach amounts which will enable those trades to provide each of them with a professorship, a chair or a scholarship, and in that way for ever to connect their name and their industry, and show their interest and create a relationship between themselves and the new institution.

Donations amounting to 95,244*l.* were promised, including 20,000*l.* from the Brewers' Fund.

THE VENUS OF MILO.

AT the annual meeting of the Hellenic Society a paper by M. Reinach was read respecting the statue known as the Venus of Milo in the Louvre. He said he thought he had solved the riddle of the restoration of this Aphrodite. In 1892 M. Ravaisson published a photograph of a drawing of the statue as it was in 1819, the time of its discovery. On either side was a beardless Hermes with inscriptions. The first of these was the one that fixed the date at 260 B.C., but the other which contained the name Theodoretas was not as late as the middle of the fourth century. There was, therefore, an Aphrodite with two Hermes, one having an inscription of 260 B.C., the other of 370 B.C., but there was no reason for dating the statue from one rather than the other, since neither of the inscriptions was on it. Now, in 1877 a number of statues were found together in Melos, which M. Tissot, then French Minister at Athens, tried, without success, to get for the Louvre. They included a colossal statue of Poseidon, some parts of female statues and a statue bearing the name Theodoretas. The conclusion was that this remarkable statue of Poseidon of Melos belonged not to 50 B.C., but to 370 B.C. All those who had seen the two were struck by the resemblance that existed between this Poseidon and the Aphrodite of Melos in technique and in the folds of the draping, and some authorities had attributed them both to the same period. Having thus got to the opinion that the Aphrodite and the Poseidon were of the same period and technique, and had come from the same workshop, he conceived the idea that they must be combined in some way, not as a group, but as a pair. Now, it had been suspected that there was something wrong in the designation of the Paris statue, and when the matter was considered, the name was seen to rest on little or no evidence. His theory, then, was that this Aphrodite was not an Aphrodite at all, but an Amphitrite. That would go very well with the idea that she was associated with Poseidon, and would help towards the proper restoration of the Paris statue. The great difficulty in restoring the Venus of Milo was that she seemed to be looking a long way away, and that her regards were directed upwards. For this reason re-

storers had not, so to say, known what to do with her eyes. But it had been observed that the statues of sea divinities often seemed to be looking as if they were examining the distant horizon and this fact might be a clue in the case of the Venus of Milo. The statue of Poseidon had the right hand uplifted and holding the trident, while the left hand was approaching the body as if to take up the draperies. The Aphrodite might be taking up the draperies with the right hand and holding the trident in the left, and so the two might be imagined as responding to each other. The fragment of an arm holding an apple, exhibited with the Venus, he refused to take into account; it was not found at the same time as the statue, and its work was very poor. As a last consideration, he pointed out that Philochorus spoke of two big statues in Telos representing Poseidon and Amphitrite. At first M. Reinach thought Telos might be a mistake for Melos, but further reflection convinced him this was not the case. The statement of Philochorus showed, however, that about 400 B.C. there were two statues of Poseidon and Amphitrite associated together in the adornment of a shrine, and it might be that about the same time a shrine of Poseidon in a neighbouring island—Melos—was adorned with two similar statues at the expense of a rich man named Theodoretas.

ARTISTS' COPYRIGHT.

ON Monday the select committee of the House of Lords on the Copyright Bills now before that House heard two witnesses who gave evidence on the question of artists' copyright.

Mr. Arthur Lucas, art publisher, who attended as a delegate from the Printsellers and Art Publishers of Great Britain, said those he represented offered a hearty general support to the Bill of Lord Herschell, recognising in it a serious attempt to consolidate and amend the law, which was very desirable. Art publishers were persons who purchased an artist's copyright, got the picture, and engraved and sold the reproduction, taking all the risk. With reference to the question of copyright in artistic works, he submitted that some amendment was required in the clause which provides that public exhibition for reward, or the first offering for sale or hire, or of any copy, should for the purposes of the Act be deemed publication. There should be a definition of what should constitute publication so as to prevent the exhibition of a picture in the Royal Academy from being deemed publication for the purpose of conferring copyright. At present copyright in an engraving endured for twenty-eight years; the engraving was a new work and nobody else could engrave it, but he wanted power to protect the picture from being reproduced by any other process, *e.g.* by photography. More stringent powers were required to deal with the sale of pirated engravings. These things were sold in first-class carriages and in first-class provincial hotels; the vendors called on great mercantile establishments, public offices, and wherever they could get access. The difficulty of running to earth these pirates was very great. Their lordships, he was advised, hesitated about giving power summarily to arrest, but, however that might be, the present powers were very ineffective to put down the grievance, and costly as well. He remembered a case a good many years ago at Wimbledon where a man selling these pirated engravings refused to obey an ordinary police-court summons. Detectives were employed, who traced the man home, where, on being arrested, he created a great scene, his wife and daughters falling on his neck and crying, while in the meantime the negatives were spirited away out by the back door. The man was fined to the amount of 70*l.*, but this did not stop his business, for he transferred himself and his negatives to Jersey, and for years distributed through the Post Office pirated copies of artistic publications throughout the United Kingdom broadcast. In dealing with such a class of men a power of summary arrest seemed necessary, because they never responded to a summons. The pictures, too, on seizure should be forfeited.

Lord Thring: Do you think they should be seized whether the person got them innocently or not?—They should be, but publishers never would do so. I have seen even in my family doctor's rooms piracies of copyright publications. I do not desire to bring up the innocent buyer or seller, only we do not believe the seller ever is innocent.

Mr. E. Bale, artist, member of the Institute of Painters in Water-Colours, gave evidence on behalf of the Artists' Committee on Copyright. His view was that there should be no stipulation as to publication in order to secure copyright. The copyright should date from the moment the artist put his brush or pencil to the canvas, and the term should be a fixed period ending so many years after the artist's death. If, however, the artist was not a British subject, then, to secure copyright, he must have made or published it in some part of the British islands. Reproductions should be registered, and the author of such reproduction should have copyright for a certain number of years from the date of registration. A sculptor who made an original work should have a longer copyright than the sculptor who merely made casts from nature. If, therefore, thirty years was granted in the case of reproductive works, then a longer period should be given to original works. The committee he represented were in favour of compulsory registration of assignments of copyright. Six months ought to be allowed for such registration, and even after that time it ought to be possible to any person to whom copyright was assigned, if for any reason he had failed to register, to go before the court and obtain leave under terms to register. With regard to the term of copyright, artists did not understand why they should lose a considerable part of their copyright if they did not paint under their true name. It was not an uncommon thing for an artist to paint under a *nom de guerre*. The witness took strong exception to the clause declaring public exhibition for reward, or the first offering for sale or hire, or of any copy, to be publication for the purposes of the Act. This, he said, would create great difficulty in the case of presentation works and the like that were never exhibited for sale or hire. There was a picture of Sir Henry Irving by Sir John Millais in the Garrick Club. It was never exhibited for reward and never offered for sale or hire. There was no statutory copyright in that picture under this Act, but suppose a photographer were to photograph, by permission of the committee of the club, the picture, for the purpose of illustrating an article on the works of art in the club, he would gain a copyright in the photograph as a work of art under this Act.

Viscount Knutsford: Of course the committee might give anybody else a right to photograph the picture?—I do not think they could in the circumstances, because he has produced a work of art which gives him a copyright for his life and thirty years. He did not believe such was the intention, but he thought such was the effect of the Bill as drawn.

The witness also took exception to the provision giving the owner of the copyright in an artistic work the exclusive right to exhibit the work publicly. This might prevent such an exhibition as the recent one of the works of Sir John Millais, and the artists' committee did not think the copyright owner should be able to prevent the owner of the picture from exhibiting it.

Lord Thring: When you buy an article do not you think you have the property in it for all purposes whatever?—Generally, yes.

I want to know why, when you buy a picture, you should not have full property in it in every respect the same as in other articles?—The reason is that there are two properties and not one, and it often happens that the copyright is the more valuable of the two. When a man comes to buy a picture, it seems exceedingly unfair that because he buys a picture, which can be sold quite apart from the copyright, it should be taken for granted that he buys also that which is an even more valuable property. The copyright should not pass unless it is clearly so understood.

Lord Thring: I have no objection if you throw the onus of making the statement on the artist.

The witness, in further examination, said artists wanted to have something to say about the quality of their reproductions. Cases had occurred where an artist had been able to prevent bad reproductions of his work, in which he had been greatly interested.

REBUILDING OF CENTRAL FLORENCE.

THE British Consul-General Chapman, in his report to the Foreign Office, says:—

The rebuilding of the centre of Florence was first begun in 1888, and will be finished in 1899. The final project was drawn up by a commission appointed for that purpose by the municipality, who in their work followed the lines of a previous scheme approved by Royal Decree of April 2, 1885.

It consists approximately of a square surface, blunt at its north-eastern angle, the right side being that tract of the via Cerretani lying between piazza del Duomo and via Rondinelli, the upper side consisting of that branch of the via Tornabuoni situated between via Rondinelli and piazza Santa Trinità, the left side being constituted by the via Porta Rossa, and the lower side by the via Calzaioli. On the left the modifications extend somewhat beyond the given limit as far as the via Vacchereccia. At about 54 yards from the via Calzaioli lies a regular square (piazza Vittorio Emanuele), and parallel streets intersect the area in a southward and eastward direction, the main streets being southward via degli Strozzi, prolonged by via degli Speziali and eastward via Pellicceria, both of which cross in the centre at right angles by the upper side of the square.

The project, although intended to clear out the more central quarter of the town from heaps of old houses and trace larger and regular streets, had at the same time in view the arrangement and good environment of some important monuments like the church of Or San Michele, the Palazzo Strozzi, the church

of St. Gaetano, as well as the many old interesting palaces spread thereon, as that quarter of the town, being the oldest and more central, was once inhabited by the wealthiest and most powerful families of the Florentine Republic.

The area expropriated for the rebuilding of the centre is 51,428 square yards, besides the existing streets; the number of expropriated buildings is 356, with a total expense for the commune of 320,000*l.*; the number of streets is 16, their total length about 2,516 yards, and their average breadth 46 feet.

The Palazzo Strozzi, so remarkable for its grandeur as well as for the exquisiteness of its cornice constructed by Simone del Pollajolo, has greatly benefited by the change owing to the widening of the square at the back of it. The most interesting palace of Palla Strozzi in front of the above, by some attributed to Brunellesco, by others to Michelozzi, the architect of Palazzo Riccardi, though not yet finished, has likewise much benefited by this square, and will soon be repaired and completed. The large Archiepiscopal Palace, which was entirely hidden among heaps of miserable houses within the old fruit market, has been entirely freed, repaired and to some extent rebuilt. The baptistery opposite to the above palace was likewise greatly benefited by the considerable widening of the square round the church; the Palazzo Vecchietti (La Carolaia), the Casa dei Sassetti, and the Casa Lamberti were also thoroughly repaired and restored to their original state by order of the municipality, who, in selling the expropriated properties, obliged the buyers to rebuild any historical building that might be included in the lot. The Palazzi Medici-Tornaquinci, Orlandini del Beccuto, and others were repaired by the proprietors of their own accord, whilst the Palagio dell' Arte e della Lana and the Torre dei Foresi are not yet, but will soon be thoroughly restored to their former condition.

The extension of the city towards the east, considered the most pleasant and healthy part, has been heretofore delayed by the Florence-Rome Railway. The necessity of displacing this line had been fully anticipated and provided for thirty-two years ago in a general plan for enlarging the city, approved by Royal Decree, dated September 19, 1866. The removal of the capital to Rome had, however, caused the question to be postponed, and it was only in 1889 that a new project was brought forward, and this was followed by the construction of a new traffic station near the Campo di Marte in substitution of the "Croce" station, and the displacement of the line itself between the Affrico and Mugnone which was completed in 1896. Before opening it to traffic the commune made a convention with the Government to concentrate in the new station all the goods traffic previously discharged at the central station (Porta a Prato). The total estimate for the entire execution of the works was fixed by the High Council of Public Works at 270,927*l.*, the Ministry of War contributing 10,000*l.* and the commune 56,000*l.*, including the value of the ground given up to the Government. The latter, on the other hand, gave up to the commune the area occupied by the old branch of the line so displaced amounting to 102,856 square yards.

In order to facilitate the building of the new station the commune took upon itself to proceed to the expropriations of further ground required for the same with the payment by the Government of a lump sum of 10,000*l.*

The amount expended up to the present amounts approximately to 88,000*l.*

According to the above-mentioned convention, the Government is bound to carry out all further necessary works before the year 1900, when there will remain 5,200*l.* to be expended in order to complete the project of 1889.

In connection with the displacement of the Roman Railway and the consequent construction of the Piazzola bridge in substitution of the level crossing of the Querce, the commune has incurred an expenditure of 20,000*l.*, viz. 7,200*l.* for the displacement of the octroi boundary (cinta) and gate (barriera), and the remainder for expropriations. The above bridge has reduced to two only the five level crossings that were on the line between the Affrico and Mugnone, to the great advantage of railway shunting and inter-communal transit. The wooden structure temporarily made for passenger traffic at the Campo di Marte station will be replaced by a proper stone building.

A scheme is now on foot with a view to improving the central station, for which the Government assigned a sum of 12,000*l.* and the commune 2,400*l.* It is, however, anticipated that these amounts will prove entirely inadequate for the purpose. Owing to its situation in the centre of the city this old station is specially adapted for passenger traffic, which explains the interest now being taken in Florence as to the best means of enlarging it and rendering it more suitable to its purpose.

At the same time that the works in the centre of the city were being carried out, attention was devoted to the improvement of the buildings and streets of the Quartiere di San Frediano, the poorest in Florence, and the actual refuge of that part of the population driven out from the Ghetto and the old market. These works will not be completed for some time. However, part of the old city walls on that side have already been pulled down to put the quarter in more immediate contact with the town, a new gate called "Barriera di Bellosguardo" opened, a large square formed, and many houses expropriated for future changes. These preliminary works are intended to be followed by more substantial improvements of the houses and streets of this populous quarter.

THE NATIONAL GALLERY.

THE portrait of Mr. Gladstone, by Sir John Millais, which has been presented to the nation by Sir Charles Tennant, has been placed in Room 21 in the English wing of the National Gallery, where it will, no doubt, be a source of great attraction at the present time.

The portrait by Ambrogio de Predis, said to be of Francesco Archinto, which is now being exhibited in the collection of works of the Milanese School at the Burlington Fine Arts Club, has been purchased for the national collection. It will be placed, after the close of the exhibition, in Room 9 in the National Gallery.

The late General John Julius Johnstone has left by bequest to the National Gallery a portrait of a lady and child and a sketch portrait of Lady Hamilton, both by George Romney, and two portrait heads of Mr. James P. Johnstone and of Mr. Alexander P. Johnstone, both by Sir William Beechey. Colonel the Hon. F. W. Stopford has presented a portrait by Romney of Lady Craven, afterwards the Margravine of Anspach. They will be placed in Rooms 18 and 20 in the English wing.

REGULARITY IN FORMS.

WHEREVER we discover fitness or utility we infer the existence of design. In those forms accordingly which are distinguished by such qualities, the discovery of an end immediately suggests to us the belief of intention or design, and the same material qualities of form which signify to us this fitness or usefulness are the signs to us also of the design or thought which produced them. It is obvious, however, that we often perceive the expression of design in forms, both in art and nature, in which we discover neither fitness nor utility. By what means then do we infer the existence of design in such cases, and are there any qualities of form which are in themselves expressive to us of design and intention? Probably because there are certain qualities of form which are immediately and permanently expressive to us of these qualities of mind, and which derive their beauty from this expression. In this view it will easily be observed that the material quality which is most naturally and most powerfully expressive to us of design, is uniformity or regularity. Wherever in any form we observe this quality, we immediately infer design. In every form, on the contrary, where we discover a total want of this quality, we are disposed to consider it as the production of chance or of some power which has operated without thought or intention. "In all cases (says Dr. Reid) regularity expresses design and art, for nothing regular was ever the work of chance." In what manner this connection is formed, whether it is derived from experience or to be considered as an original principle of our nature, we need not inquire. It is, however, very obvious in children at a very early age, and it may be observed that the popular superstitions of all nations are in a great measure founded upon it, and that all uniform or regular appearances in nature are referred by them to some intelligent mind. The terms regularity and uniformity are used so synonymously that it is difficult to explain their difference. With regard to both terms, when applied to forms two things are observable. First, that they are only applied to such objects as compose a whole, and that they express a relation either between the parts of it considered separately or among the parts considered as constituting the whole. The relations between different wholes or the parts of different wholes are expressed by other terms. Second, that they express always similarity or resemblance of parts. With regard to uniformity the term itself is an evidence of it, uniformity being nothing but similarity of form. With regard to regularity it is not less evident. A regular form is a form where all the parts are similar, an irregular form is a form where all the parts are dissimilar. A form partly regular and partly irregular is a form where some parts are similar and others dissimilar. There is, however, another meaning of the term when applied to works of art, viz. the imitation of a model. Thus, we say that a pillar is regular, that a poem is regular, that any composition is regular when they have the same proportions and the same parts which are found in the model or prescribed by the rule. In this case it is still the similarity of parts which constitutes regularity, the similarity between all the parts in the copy and those in the original from which it is borrowed.

NOTES AND COMMENTS.

Florence, like so many other cities, has found it necessary to sacrifice a great many evils which years had respected. In course of time it will be nearly all modern with the exception of a few buildings. The British Consul says that those who recollect what Florence was fifty years ago can only adequately appreciate the great improvements made during that period. The via Gora once occupying part of the present via Montebello, the Camaldoli of St. Lorenzo, pulled down for the erection of the central market, San Frediano and San Niccolo, now partly improved, and the Ghetto, also pulled down, were the receptacles of dirt and misery. Hundreds of families lived and died there without ever coming out of those filthy and narrow streets. The public slaughter-house was situated within the city walls. There were no public closets, houses were unprovided with pipes to receive the rain from the roofs, with the result that on rainy days the water noisily poured into the public streets, flowing in large rivulets along the same; the sewers, too small to receive the drains, caused large puddles in many places in the town; moreover, being connected with the river, within the gates, they overflowed during heavy rains, inundating whole streets. No drinking water was available but that of the wells, the supply of the Montereggi aqueduct being insignificant, and the soil was continuously contaminated by the filtrations of cesspools and old sewers. This state of things, which had existed for centuries, has for some years entirely ceased. At present the drainage of the town, if not always that of the houses, is good; the water supply will soon be, by the new project, one of the best in Italy; lurid and narrow quarters which were a den of infection have almost all disappeared under the pick of industrial contractors, who have erected in their place large buildings with all modern comforts; small airy houses for the poor have also in many suburban quarters been erected. It is also to be hoped that the law of December 22, 1888, on hygiene, instituting a special sanitary department attached to each municipality, prescribing special provisions for house-building, for public disinfection, for the sequestration of unwholesome and adulterated alimentary products, and a special and strict surveillance on all matters concerning hygiene, will permanently secure to Florence the full fruits to be obtained through the above improvements as far as public health is concerned.

Of late years important improvements have also been carried out in the Florence galleries and museums. At the "Uffizi" the decoration of the Niobe room was restored and the paintings substituted by old tapestry. The jewellery room was entirely rearranged. Two new rooms were opened for sketches, pastels, and miniatures; but the most important improvement was the new arrangement given this year to the collection of portraits of painters, which were disposed chronologically, and at the same time according to nationality. In consequence of the opening of these rooms, a double staircase leading from the first to the upper floor was added with a view to rendering more imposing the access to the vestibule. The bas-reliefs of the Rapace Salustre kept therein were removed and replaced by four tapestry hangings, the former being placed, together with the collection of busts of the princes who have encouraged the gallery, in the room of the Hermaphrodite, substantially improving the arrangement of the latter and of the adjoining room containing inscriptions, statues and busts. In the Ancient and Modern Gallery (via delle Belle Arti) three rooms were added, one called the "Perugino" after a large picture of that master (*The Assumption*), and the other two rooms taking their name from "Botticelli," because they contain several pictures of that painter. The large room (Salone) was divided into three rooms called "of the Tuscan masters," where the works of the chief Tuscan painters from the thirteenth to the eighteenth centuries were arranged and classified. A new staircase leading to the Palatina Gallery was built in the Palazzo Pitti after the design of the late Professor del Moro, the architect who superintended the building of the façade of the cathedral, unveiled in 1887.

If Belgian manufacturers cared to imitate and adopt the ordinary English methods of making their productions known in this country they would be able to reckon on most profitable results. The business done by them at present passes through several hands, and the profits are therefore sometimes divided to an excessive extent. The Consul-General of Great Britain at Antwerp, in his last report, says he is "constantly in receipt of letters from buyers in Great Britain and the Colonies asking to be placed in communication with manufacturers of iron and steel girders, engineering plant, &c., which the comparatively cheap rates of wages and longer hours of labour enable Belgian manufacturers to furnish on advantageous terms." The demands are not confined to officials. We know of one expert at least who, when consulted, steadily declined to recommend any of the manufacturers of girders in Belgium, because he said he was without any certainty that his clients would be dealing with the people he had in view. The Belgians do not announce what they can supply, and consequently when they receive orders several commissions have to be deducted. Reciprocity should mark the dealings of both countries. The British Consul says that in engineering tools and labour-saving appliances English manufacturers could successfully compete with Belgian engineers. According to him, "Articles of this kind, if properly pushed by competent agents or by the personal exertions of principals, would, I think, find a favourable opening in Belgium; it is impossible, however, to lay too much stress on the importance of adopting a wise mode of introducing such articles."

Amidst the numerous archæological puzzles which await solution there is not one which is more mysterious than the origin of the great architectural and engineering works which are to be discovered in parts of South America, which otherwise would appear to have been always in the depths of barbarism. They are so wonderful as examples of construction that modern go-ahead engineers cannot ignore them. A few weeks ago a paper was read before the American Society of Civil Engineers by one of the members, Mr. R. B. Stanton, on "The Cliff Dwellers of the Far South-West: their Homes, their Agricultural and Engineering Works, and their Military Knowledge and Art." During professional excursions in Arizona and New Mexico, Mr. Stanton collected data about the habits, development and conditions of the races that inhabited that region. He believed that they were a superior race, mentally and physically, and well advanced in arts and industries, particularly in constructional skill. The excellence of their dry masonry, which has endured for thousands of years, and still shows careful design and construction, was remarkable. Some of the houses contained as many as 100 or more rooms, from 10 to 40 feet square, and were as high as seven storeys. There are also remains of great irrigation works that comprised dams and controlling works that would be creditable to modern designers, and canals having capacities up to 50,000 inches of water and lengths up to 100 miles. One of them was cut through solid rock to a depth of 20 or 30 feet for many miles, and without evidence of the use of metal tools or other instruments than the stone axes. Mr. Stanton came to the conclusion that the builders were of the same race as the men who erected the great structures of Yucatan. The late James Fergusson believed that the old Mexicans were nearly allied to the Esquimaux, while some were of the Red Indian variety. The Aztecs especially represented the latter. But in Yucatan there was undoubtedly another race that might have been Caribs. The Polynesian element is, he adds, strongly developed in Peru. As regards architectural forms Fergusson said that no one would be startled if told that the representations of some of the temples in Cambodia were derived from buildings in Yucatan, whilst many of the crinkum-crankums of Chinese builders have their counterparts in America.

CATHEDRAL SERIES.—PETERBOROUGH: FROM PALACE GROUNDS: RETRO-CHOIR.

THE NATIONAL PROVINCIAL BANK OF ENGLAND, PICCADILLY.

Our illustration exhibits the effect of the faïence work supplied by Mr. Alfred Whitehead, of Prudential Buildings, Leeds, from the designs of the architect, Mr. Alfred Waterhouse, R.A.

PETERBOROUGH CATHEDRAL.

THE following description of the interesting fan vaulting of Peterborough Cathedral, by the late Professor Willis, reveals arrangements which are not apparent to visitors. It forms part of his essay on the "Construction of the Vaults of the Middle Ages," published in the Transactions of the Royal Institute of British Architects :—

In fan vaults the difficulties of adjusting the curvatures of the ribs are at once disposed of by making them all of the same curvature. We may suppose that the increasing complication of the patterns in the vaults of the kind already described, and the great number of intermediate ribs and liernes that were thus introduced, may have led to the invention of this method, by which certainly the number of templets and the difficulties were greatly diminished. The construction of these fan vaults is in all examples so nearly the same that they seem to have proceeded from the same workshop ; and it is remarkable that, at least as far as I know, there are no continental examples of them, whereas of the previous vaults there are quite as many on the Continent as in England. In France, indeed, the lierne vaults are not very numerous, they are confined to small chapels, and their patterns are in general simple ; but in Germany and in the Netherlands there is an abundance of them, distinguished certainly from ours by local peculiarities, but nevertheless of similar mechanical construction, and requiring the same geometrical methods.

The general construction of fan vaults may be understood from the sections. These represent one of the most complete, which covers a kind of chapel at the east end of Peterborough Cathedral. The workmanship of this vault is the most perfect of any that I have examined. The span of King's College Chapel (42 feet) is much greater, but its workmanship is not nearly so good. The span of the Peterborough vault is 26 feet from wall to wall.

The pattern of these vaults is always a kind of tracery of the same class as the perpendicular tracery which at that period occupied the heads of windows or the surfaces of walls, the only difference being that the mullions, instead of being parallel and vertical, are curved and radiate from an impost. Instead, therefore, of the horizontal transoms of windows, we have level circles intersecting the ribs at nearly equal distances, and intermediate rays or ribs are inserted between the principal ones. The panel spaces into which the surface of the vault is thus divided are furnished with arch heads and foliation, exactly as the similarly produced panels are ornamented in the tracery of windows.

In the lierne vaults a star pattern is commonly found, which radiates from each impost in the same way as the fans of the present class of vaults. The difference between the star and the fan is that the star is formed of ribs, which may be and often are of different curvature, and the rays of the star of different length, but so skilfully arranged with regard to their solid effect that, although irregular upon the plan, this irregularity is not offensively perceived in the complete work.

The fan is, on the other hand, formed of ribs strictly of the same curvature and elevation, and its outline is bounded by a horizontal circular rib instead of the zigzag line of liernes in the former vaults by which the rays of the star are pointed. The effect of the fan is that of a solid of revolution upon whose surface panels are sunk ; the effect of the star is that of a group of branching ribs. This difference of character is assisted by the mode in which the mouldings are disposed in the two cases. In the older vaults a vertical plane upon the plan line of every lierne or rib divides it into two symmetrical halves ; but in the fan vaults the moulded rings and arch heads are all perpendicular to the surface of the vault. This will be more fully explained presently.

In fan vaults the quantity of decoration is so much increased and its parts become so small that it is no longer practicable to frame the tracery of these vaults on the rib and panel system with liernes and boss stones, and consequently the portions near the crown of the vault, where the decoration is compressed and crowded, are always constructed of jointed masonry. But the branching ribs below the first series of arch heads are still built of long stones filled in with panels, and the *tas de charge* from whence the ribs spring is also laid in level courses as before. There are a few exceptions to this general description ; for example, the vault of Henry VII.'s Chapel, which, however, differs in many other particulars from these fan vaults, and will be separately described. It is entirely constructed of jointed masonry without panels. Also the vault of Islip's Chapel at Westminster is a real fan vault, but without any mixture of rib and panel-work.

In fig. 1 the upper half of the plan represents the lower surface of the vault with the joints of the masonry and pattern of the tracery, and the lower half shows the upper surface of the vault with its joints. Fig. 2 is a vertical section through A C, and fig. 3 an isometrical projection of the upper surface. The portion of vault included within the spandrel A B C, consisting of plain ribs only, is constructed of rib and panel-work exactly like the older vaults ; but all the remainder of jointed stonework, as shown in the lower plan. In the King's College vault, and in many others, the short straight portions of rib that lie between K and L are also constructed in separate stones with panels dropped between.

FIG. 1.

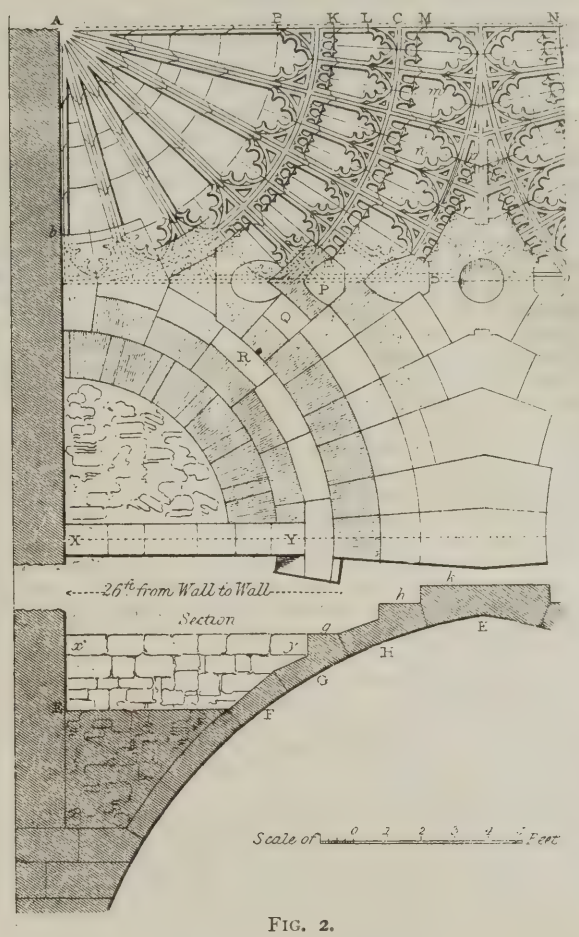

FIG. 2.

The section shows that the spandrels of this vault are filled up to the level of E with rubble-work, as are also the spandrels of King's College vault. In addition to this, a wall xy is at Peterborough added to stiffen the spandrel. This I have not seen elsewhere. Every one of the stones of the jointed masonry retains a portion of the horizontal surface of operation, which in this construction is evidently employed for the same purpose as in the boss stones of the lierne vaults. These horizontal surfaces are indicated upon the plan by the light tint, and are also shown in the section at g, h and k, and more clearly in the perspective drawing, fig. 3.

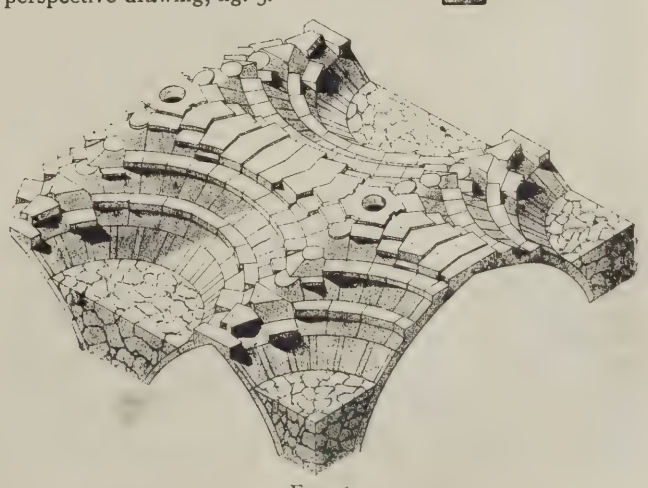

FIG. 3.

The joints of the masonry are evidently arranged with reference to the pattern of the vault. Thus a ring of stones round A, beginning at B K, is made to contain all the first series of panel heads, with the circular rib and crown of Tudor flowers. The succeeding ring from K M contains the next series of panels, with their arch heads and the Tudor flowers above them. As to the next ring, it begins at M N by extending

across the crown of the arch, and when the stones become too large they are divided, as at *m n*, *p q* and *r s* in such a manner as to interfere as little as possible with the lines of the pattern. It is remarkable that the masons of this period often place a joint in the very middle of a projecting rib, as at *p q*. As to the radiating joints they lie in this example in the middle of the panels, but in others not universally so. Since the disposition of the joints is thus governed entirely by the pattern of the tracery, it is clear that in setting out the moulds of the stones the lower joints must first have been drawn upon the plan, and then the moulds of the upper surfaces obtained from them by a system of projection similar to that which I have already applied to the lierne vaults and bosses.

It must be supposed that the lower surface of the stones was worked smooth, and the lesser ornamental details drawn upon this surface, so that for the purpose of settling the places of the joints only the ribs and circular bands were drawn on the plan, for if the entire pattern were drawn on the plan and transferred to the surface of the vault by projection, as in the case of the complex lierne vaults, the arch heads, circular panels and other figures which decorate the spaces between the principal lines would be distorted after the manner of the squares in the choir vault at Wells Cathedral. But such distortions never appear in these figures in fan-vaulting, so that we may assume that these details were traced upon the lower surface of the vault stones, but that all the principal lines necessary for obtaining the form of the stones and distribution of the joints were projected from the plan. Indeed, the new manner in which the mouldings are worked, namely, perpendicular to the surface of the vault, as already mentioned, shows that the patterns were now drawn upon and sunk into that surface, and not derived from the plan.

I will now explain the steps by which I suppose the shapes and moulds of the stones to have been obtained, and which in principle is the same as the method by which I have obtained the boss stones and liernes, namely, by means of the horizontal upper surface of operation, of which there is abundant evidence to prove the employment in all the existing specimens of fan-vaulting of which the upper surface is accessible.

Fig. 4 explains this method, and corresponds in the plan of the vault to fig. 1, the examples chosen being the stone marked P and those which correspond to Q and R on the opposite side of the ridge rib.

On the plan fig. 4, the ribs and circular bands being inserted, as shown by the double lines, draw A B the central line of the rib upon which the stones in question lie, and upon it draw in elevation C D, the curve of the rib, which, from the nature of fan-vaulting, is the same for every rib.

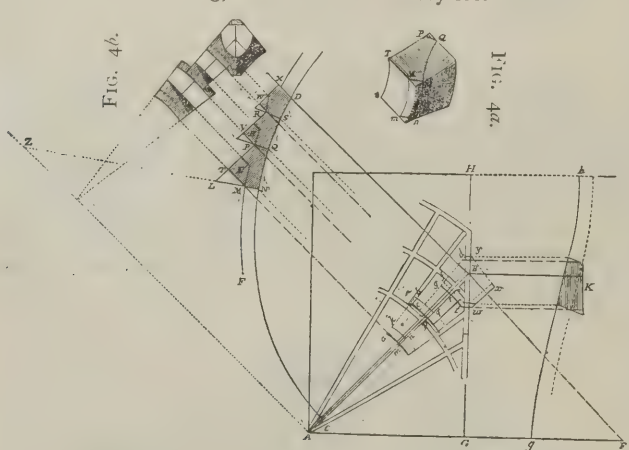

FIG. 4.

The joints at the lower surface must next be drawn upon the plan, as shown by the dotted lines, due regard being had to the ornamental details which are to be subsequently added. These joints are either radial or circular, from the nature of fan-vaulting. The radial joints which converge to the centre A are all in vertical planes, and therefore their places upon the upper plan or surface of operation will be vertically above and coincident with their places upon the lower surface, as at *a b* and *c d*. But the circular joints are arch beds,* and their places upon the upper surface may be obtained from those of the lower surface by upwards and downwards projection as follows.

The circular joints intersect the line A B at the points *n*, *q*, *s*. Project these upwards to meet the curve C D at N, Q, S. Draw F M X concentric to the curve, and at a distance from it equal to the necessary thickness of the rib C D.

From the centre of curvature of C D draw the arch joints N M, Q P, S R, intersecting their outer curve at M, P, and R; and through these points draw vertical lines M T, P V, R W, also projecting the same points downwards to the plan at *m*, *p*, and *r*. With centre A draw circular arcs *a m*, *c p*, *g r*. Thus will be obtained the plans or moulds of the upper level surface of operation of the stones N P, Q R, and the horizontal lines T P V R will be the sections of these upper surfaces.

To complete the third stone S X, however, it is necessary to draw the curve of the ridge rib, for this stone, being placed at the meeting of two ribs A B F B, and of the ridge rib G B H, resembles in this respect a boss. It is in fact upon the plan a six-sided figure, bounded by four arch joints, *g t*, *t w*, *w x*, *d y*, and two radial joints *g d*, *y x*.* The joint *w x* being opposite and similar to *g t*, the same section W S X D will serve for the two joints, but the joints *t w*, *d y*, must be obtained from the elevation of the ridge rib, which may be drawn as follows.

Since the arch ribs of a fan vault are all of the same curvature, the ridge ribs can no longer be horizontal, and their form is, in fact, determined by the intersections of the arch ribs, so that when the dimensions of the parallelogram which is to be covered by each severy of the vault, and also the curve of the rib are given, the form of the ridge rib may be found. For example, as follows :—Let A B C D (fig. 5) be one-quarter of the

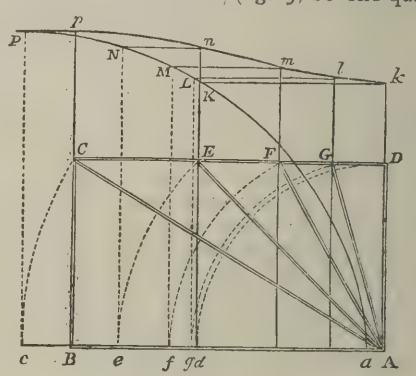

FIG. 5.

severy, A D A G A F A E A C the ribs branching from A, of which *a* K N P is the curve in elevation upon A B. A *c* is made equal to the longest rib, namely, the diagonal rib, A C; and the lengths of the other ribs are transferred by arcs of circles round the centre A to the points *d g f e* respectively. Draw perpendiculars upon these points meeting the curve in K L M N and P, then will G be the plan of the point at which the rib A G intersects the ridge rib, and A *g* is equal to A G, consequently *a* L is the portion of arch curve occupied by the rib A G, whence *g* L is the height of the ridge rib at G above the impost plane. In like manner A *e* (equal to A E) shows *a* N to be the quantity of arch curve occupied by the rib A E, and thence *e* N is the height of the ridge rib at E. Similarly it can be shown that *d* K, *g* L, *f* M, *e* N, *c* P are the respective heights of the points D, G, F, E, C of the ridge rib. Draw, therefore, perpendiculars D *k*, G *l*, F *m*, E *n*, C *p* through these latter points, producing them to A B, and also parallel lines K *k*, L *l*, M *m*, N *n*, P *p*, intersecting them in *k*, *l*, *m*, *n*, and *p*, then will the curve drawn through these points to the elevation of the ridge rib correspond to A B.

The curve so obtained being transferred to the plan fig. 4 at *g h*, the section of the stone in the middle plane of the ridge rib may be drawn, as at K, by upwards and downwards projection, in the same manner as the other sections have been obtained.

The stone N P may now be worked as follows. Having levelled the upper surface of operation, trace upon it the upper mould which has been described upon the plan at *m a c p* and also the arc *b q*. Work the radial joints perpendicular to this surface and trace upon them the side mould N M T P Q. Work a concave surface also perpendicular to the surface of operation, and meeting it in the line *a m* and a convex surface meeting it in the line *b q*. Fig. 4*a* represents the stone in the state to which it has now been brought. It is viewed angularly. *t* T P is the edge of the surface of operation, N M T P Q one of the radial sides plane and perpendicular to the latter surface, and T *t* M *m* is the concave surface, also perpendicular to the

* These beds are in fact conical surfaces, which may be obtained theoretically. Draw A Z perpendicular to A B, then will A Z be the axis of the solid of revolution or spandrel-conoid generated by the curve C D; and M N being any given arch joint of this solid, produce it to meet the axis in Z. The bed of which M N is a section is a frustum of the cone that would be generated by the revolution of Z N round the axis A Z.

* Sometimes, when the pattern of the vault admits of it, one or both of the ridge joints *d y* *t w* are omitted, and the stone brought to a point on the plan at *t w* or *d y*. This happens to be the case in the stone which at Peterborough corresponds to the one I am now describing, as will be seen in fig. 1; but as the two joints in question are very often employed I have inserted them in this place to make the description of the method complete.

upper surface. The outline of the side mould is shown traced upon the radial surface. To complete the stone it remains to form the two conical arch beds M *m* N *n* and P Q. The latter is easily wrought by tracing a horizontal line on the convex surface, beginning at Q, and then working away the stone in straight lines from this line to the arc already traced on the upper bed from P, or this bed may be worked by means of a bevel set to the angle T P Q, and thus the necessity for working the convex surface be dispensed with.

In like manner the lower arch bed M *m* N *n* may be wrought in two ways: first, by tracing from M the horizontal line M *m* on the concave surface and working the bed by a bevel set to the angle T M N; secondly, by working the lower surface of the stone into a horizontal plane passing through N and parallel to the upper surface, tracing the arc N *n* upon the lower plane and then working away the stone in straight lines from M *m* to N *n*. The bevel method being the simplest is most probably the one which was employed by the Middle Age workmen. The other method is more analogous to modern practice and is susceptible of greater precision. The two arch beds being completed, the lower surface *n* N Q is easily wrought from the lower boundary N *n* to the upper boundary which passes through Q by means of a sweep or templet whose edge is cut to the curve N Q.

A similar process will give the form of the more complex stone at the intersection B of the ribs.

In forming the boss, the stones were worked to an acute angle, by which means a superfluous angular lump of stone is left. If the upper plan of the stone had been projected as in the above method from the point where the arch joint meets the outer curve of the rib, the useless portion would have been saved and a smaller stone have served the purpose. This is a more complete and scientific process, and while the angle remaining in the Canterbury bosses and others is evidence of the ruder process, the vertical surfaces T M *m t* (fig. 4*a*), which may still be traced in the fan vaults, prove also the use of the improved method which I have just explained. In the later lierne vaults, however, this latter method is also applied to the bosses. In fact the fan vaulting was invented long after the lierne vaulting, but they continued to be practised together up to the latest period, and the improved system of stone cutting introduced by the increased complexity of the fan vaults would naturally be applied to the lierne vaults. Thus it happens that many of the later specimens of the latter are constructed with solid masonry instead of the original rib and panel method. In the view of the roof of St. George's Chapel it will be seen that the bosses were worked vertically downwards from the plan in the same manner as the stones in fig. 4.

The arch joints or beds of bosses, however, are planes, but those of fan vaults ought to be conical surfaces. This is not universally the case in practice. The joints of the vault of Henry VII.'s Chapel appear to be in many parts of the severy worked in planes. Those of Islip's Chapel are also worked in planes, as shown in fig. 6. This is a mere diagram of a portion of the fan, and therefore the joints are not projected over the mouldings.

The fans are in this example constructed entirely of solid masonry and not of rib and panel-work. A B is a wall rib, A D a diagonal rib, A C an intermediate rib, and the arch joints are planes, arranged with respect to the ribs A B A C A D so as to pass respectively through the axis of curvature of each of these ribs respectively. In other words, if the vault be divided by lines A *b* A *c* drawn through the middle of each compartment, every portion which is contained between two of these adjoining lines *b* A *c* A forms an ordinary arch with plane joints. But in

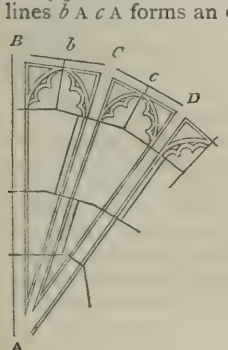

FIG. 6.

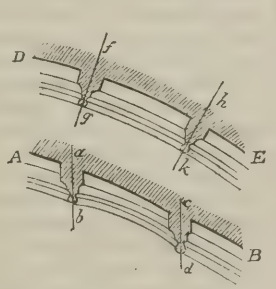

FIG. 7.

the lower stone or *tas de charge* the joint line runs obliquely across the tierceron, and beds are only provided for the wall and diagonal arches. Similar plane arch joints may be found in some parts of the smaller vaults at Peterborough, but the curvature of joints of this kind differs so little from a straight line that it is not always easy to satisfy oneself which of the two is the case, unless the joints are very accessible and decidedly marked, as they happen to be in the Islip Chapel. In the King's College vault the joints are circular and the arch beds consequently conical.

In a similar manner the panel surfaces of fan vaults which ought to be convex, and are so in many specimens, are wrought in planes in others, although the horizontal ribs are made circular. But in the fan vault of Wells tower and Islip's Chapel the horizontal rib runs in straight lines from one arch rib to the other, thus giving polygonal faces to the fans, and in these the panel surfaces are planes of course.

Fig. 7 shows the arrangements of mouldings which have been already alluded to as prominent characteristics of the two kinds of vaulting. In A B a rib is shown, which is intersected in its course by two liernes at *a b c d*. The middle plane of these liernes being as usual vertical, it is plain that their mouldings cannot mitre (as it is termed) with those of the rib, because they are placed symmetrically to their own axis, while the mouldings of the rib cross at an angle which throws them on one side below, on the other above, the corresponding ones in the lierne. This leads to great difficulties in the management of the intersections of these mouldings, which are in fact generally covered by bosses that prevent their awkwardness from being discovered; and we might fancy that it was for this purpose the bosses were invented, were it not that they are employed for the intersection of the crowns of arch ribs, in which no such difficulties occur, long before the liernes are introduced. The horizontal ridge ribs, however, which are much older than the liernes, present the same kind of difficulty in their intersection with the crowns of pointed arches. To overcome these difficulties we sometimes find, when bosses are not employed, that the mouldings of the rib are awkwardly warped and distorted at their junctions, as from *d* to *b*; also that the plain side of the lierne is several inches higher on one side than on the other, as at *a*, or else that the surface of the vault is dropped on one side to accommodate the lierne, but which introduces a similar difficulty with the rib, as at *c*. Nevertheless the branching and independent character of the ribs and liernes is so intimately bound up with this verticality of their middle planes, that I cannot help ascribing one of the first departures from the true Gothic character to the change in the method of intersecting the mouldings, which is the leading feature of fan groining.

This is shown at D E, where a rib of the same profile as A B is intersected by two others, *f g h k*, and by placing their axes of symmetry or middle sections perpendicular to the surface of the vault, a perfect mitring of the mouldings is obtained, and the workmanship of these mouldings is at once greatly simplified and reduced to the capacity of a much lower class of workmen. But thus the ribs and other moulded lines become at once visibly referred to the general surface of the vault and subordinate to it, decorating it nearly after the same fashion and principle as the panels and concamerations of a Roman vault, which are in like manner sunk perpendicularly to the general surface; whereas, in a genuine Gothic vault, the real surface should be subordinate to the branching ribs, and rest upon them.

In some of the lierne vaults subsequent to the introduction of fan vaulting, the liernes are worked perpendicular to the surface of the vault, as, for example, in the porch of Bishop Booth, at Hereford (1516-35).

The practice of thus working the mouldings and ribs square to the surface may possibly have originated with the makers of shrine-work and small canopies, which are often ornamented with very elaborate models of vaults. These are beautifully ribbed into patterns, and as the entire vault is worked out of a single stone, the mouldings are naturally sunk with reference to its surface. In the larger canopies of monuments, too, a similar method is often followed. Thus the monuments of Archbishops Stratford and Sudbury, in Canterbury Cathedral, have canopies vaulted with small lierne vaults very nearly alike, but in the former the mouldings are vertical, and in the latter square to the surface. Stratford died in 1348, and Sudbury in 1381.

In all the great fan vaults the surface of operation is reduced by cutting away a considerable portion of the stone so as to bring it to the form which is shown at fig. 4 *b*, and also in the isometrical view, fig. 3. This is effected by removing the portions marked E in fig. 4. The remaining part of the surface of operation retains lines drawn in the direction of the ribs, as shown in fig. 4 *b*, but which are not inserted in the other drawings of the complete vault, to avoid confusion between them and the joint lines.

This portion of the stone appears to have been removed to lighten it, for from the rude and irregular manner in which it is cut away, and from the remains of the vertical surfaces T M *t m* at the lower parts of the stones, it is clear that they were first worked completely into the form shown in fig. 4 *a*.

A Church is being built at Ystrad Meurig, Cardiganshire, in memory of an eminent schoolmaster who lived in the last century, named Edward Richard. The memorial-stones have been recently laid, with inscriptions in Welsh, English and Latin.

THE SOCIETY OF ARTS.

THE annual meeting of the Society of Arts was held on Wednesday last week. We take from the report of the Council the following extracts :—

In accordance with the usual practice, the Chairman of the Council, Major-General Sir Owen Tudor Burne, opened the session with an address. On the previous occasion, last year, the Chairman selected India for his special topic ; for the session which has just been completed he devoted his address to a review of the growth and present position of the "Arts, Manufactures and Commerce of our Colonies."

At the first meeting of the session, after the opening address was delivered, Professor Douglas read a paper on "The Progress of Metallurgy and Metal Mining in America during the last Half-Century." In it he may be said to have supplemented his recent course of Cantor lectures on American metallurgy, and laid special stress on those points in which he considered American practice to be in advance of that of the old country. On the whole Professor Douglas left the impression that he considered American practice to be distinctly superior to English, but this view was rather controverted in the discussion which followed his paper. A fortnight later Mr. Bennett H. Brough gave an account of "The Mining and Metallurgical Industries of Sweden as shown at the Stockholm Exhibition," at that time just closed. On previous occasions Mr. Brough has described to the Society the metallurgical sections of the exhibitions at Buda-Pesth in 1885, Barcelona in 1888, and Kimberley in 1893. The Stockholm exhibition was almost entirely devoted to those special industries, and consequently afforded an excellent opportunity for a review of their present condition.

In the other meeting, which was held before the Christmas recess, Professor Leonard Waldo, who read a valuable paper in 1886 on American watchmaking, gave an account of "The Theory and Practice of the Manufacture of the Bicycle in America." This was one of two valuable papers on the subject, for at the end of the session Mr. J. K. Starley, who is well known for the very large share which he has taken in the development of the modern cycle, gave an account of "The Evolution of the Cycle." In the former paper, Professor Waldo showed how thoroughly systematised the manufacture of bicycles in America now is, and described the elaborate machinery which has been laid down for the purpose by the Pope Manufacturing Company at Hartford, Connecticut. One of the peculiar features of the manufacture is the very complete system of tests which has been devised for insuring the strength of the different parts of the machine. Professor Waldo also described the new method of construction adopted by the company, in which a shaft with bevel gearing takes the place of the ordinary chain running over a pair of chain wheels, by which power is transmitted from the crank axle to the hind wheel of the machine. Such a method of transmitting power can only be employed when the bevelled wheels are cut with the utmost accuracy, and Professor Waldo stated that the machinery now used for this purpose in America had got over this first and greatest difficulty. Mr. Starley's paper was mainly historical. It gave a clear and careful account of the various stages by which the modern bicycle has been evolved, if not from the ancient hobby-horse, at all events from the original "bone-shaker" of Lallemont, produced about 1865. It is a useful thing that the history of an invention should be put on record by the original inventor, and in any future account of the origin of the safety bicycle, Mr. Starley's paper will certainly have to be largely drawn upon.

Three papers dealt with subjects of a more or less photographic character. Mr. Eric Bruce gave an account of the ingenious apparatus which he has devised for what he terms "The Projection of Luminous Objects in Space." An ordinary magic-lantern picture is projected upon a revolving wheel or lath, the rapidity of the revolution being such as to enable the whole picture to be seen in consequence of the "persistence of vision," while the moving lath does not entirely obscure any object in front of which it is placed. Various curious effects may be thus produced which will probably be available for stage purposes. Mr. Jules Fuerst described "The Cinematograph" constructed by Messrs. Lumière, and gave numerous illustrations of what are popularly termed "animated photographs," certainly the most remarkable of the recent developments of photography. Captain Abney, in his paper on "Photography and Colour Printing," gave an account of the application of photographic methods to the selection of those particular tints which, by their proper combination, can be made to give all the necessary hues for the production of pictures in colour. The process of three-colour printing, though it has long been known, and has for long been the object of research on the part of many earnest workers, has only of late been practically developed, or come into actual commercial employment.

Only one paper during the session was devoted to a sanitary question—that by Dr. Rideal on "The Purification of Sewage by Bacteria." The actual nature of the action of bacteria on sewage has only lately become an object of study, but its practical developments promise results of very great importance in the immediate future. Dr. Rideal gave a very clear account of the position which the subject has reached, and showed how great the practical usefulness of the methods adopted was likely to become.

In contrast to what has been the programme of recent sessions, only a single paper was devoted to a subject of an electrical nature—that by Professor Silvanus Thompson on "Telegraphy Across Space." Professor Thompson gave a most lucid exposition of the different methods which have been adopted for transmitting telegraphic signals without wires being laid between the two points between which the communications are to be sent, and succeeded in making a very difficult subject intelligible to a general audience.

Two papers dealt with economic matters. Mr. Provand, in his paper on "Compensation to Workmen," discussed the recent Employers' Liability Act ; and Mr. Iselin, in his paper on "The Protection of Industrial Property," described the objects and methods of the International Association for the Protection of Industrial Property, which has just held its congress in the rooms of the Society.

Professor Ewing in his paper on "Linde's Method of Producing Extreme Cold and Liquefying Air," described the remarkable regenerative method which Dr. Linde has devised, and indicated some of the purposes to which it was likely to be applied in practice. It seems hardly likely that the wonderful powers of producing extreme cold, which have resulted from the researches of Professor Dewar and others, can long be without many important applications to the arts and industries.

Captain Baden-Powell's paper on "Kites" showed the possible practical applications to military and surveying purposes of that which has always been considered but a child's toy ; and from what he said there seems little doubt that, at all events, for purposes of warfare, kites will take a useful place by the side of balloons for observation and signalling.

Mr. Clayton Beadle gave an interesting sketch of "The Recent History of Paper-making." Mr. Valentine, in his paper on "The Preparation of Meat Extracts," showed how much had been done in the condensation of nutritious material into a very condensed and portable form.

Mr. Edwin Sachs criticised the methods of modern "Stage Mechanism" in his paper on that subject, and while he showed what great advances had been made in scenic illusions, he also pointed out how in very many cases stage managers and theatrical architects had neglected to avail themselves of the resources of modern invention.

Mr. Brudenell Carter, in his paper on "Children's Sight," drew special attention to the work of the recent departmental committee on this subject, and urged the importance of proper provision being made in elementary and other children's schools for insuring that too great a strain was not put upon the sight of the children. One point which came out clearly from Mr. Carter's paper was that the children in elementary schools are far better off in this respect, as in other respects, than those in the oldest and wealthiest foundations.

Mr. Thomas Potter's paper on the "Fireproof Construction of Domestic Buildings" gained special interest from the recent disastrous fire in the City. The principles he laid down were of considerable importance, and well deserve the attention of those who are responsible for the prevention of fires in cities.

Miss Clive Bayley suggested the "Revival of Hand-loom Weaving" as providing a suitable occupation for women, and gave an excellent account of the progress which had already been made in it. She pointed out what a large demand there was for hand-made fabrics, and how easy it would be to supply this demand by means of proper organisation.

Professor Vivian Lewes added one more to the useful papers which he has given the Society on subjects connected with gas lighting, by his paper on "Water-Gas and its Applications." He gave a very full account of the process of manufacturing water-gas and of the extent to which it is now used in substitution of coal-gas. One important point raised was the danger to life of using the newer illuminant. In Professor Lewes s opinion there was little if any more risk with water-gas than with coal-gas, and in this opinion he was confirmed by Mr. Corbet Woodall, who was in the chair.

At the opening meeting (January 20), Sir Mountstuart Grant Duff read an interesting and anecdotal paper, entitled "Recreations of an Indian Official," setting forth the cultivated pursuits that occupied the leisure moments of his rule in Madras, and pointing out "some of the things which one learns incidentally by living in India if one only makes a reasonable use of even very indifferent eyes." In a very able paper, Mr. Herbert M. Birdwood described, on February 17, the origin and progress of the Bombay plague, explaining the elaborate methods so energetically carried out by the local authorities to grapple with the calamity. From the position of one whose official duties had afforded special opportunities of tracing the

influence of Sir Henry Maine's ideas, Mr. C. L. Tupper dealt, on March 10, with the Indian career of the distinguished author of "Ancient Law," his suggestive paper being followed by a discussion of exceptional weight and authority. The earthquake that a year ago devastated the province of Assam, causing the loss of some 1,500 lives, was the subject of a graphic and exhaustive paper, read on March 31 by Mr. Henry Luttman-Johnson, who was able to include in it much useful information not previously made public. On April 21 Mr. Horace Bell gave a comprehensive review of recent railway policy in India, and maintained that the time has come when State action in regard to railways should be limited to inspection and control. On April 28 an excellent and well-timed paper on "India and her Currency" was read by Sir Edward Sassoon. The session terminated on May 19 with a well-reasoned paper on "Colonies and Chartered Companies" by Sir Alfred Lyall, who contended that in the altered condition of the world trading corporations are no longer "convenient agencies for the acquisition and administration of territory."

Mr. J. Hungerford Pollen read a learned paper on "Renaissance Woodwork in England" at the first meeting of the section on January 25, in which he described from the architectural point of view the beautiful woodwork in the old mansions spread about the country. The subject was further illustrated by a fine series of lantern slides showing many of the halls with their grand panelling, screens, fireplaces, &c., which were lent by the Science and Art Department.

Mr. Cyril Davenport gave a full description of the various objects of "The English Regalia" in a paper read on February 22, which was illustrated by lantern slides taken from photographs, and coloured by Mr. Davenport in a remarkable manner, so that the individual precious stones were seen in their natural colours.

At the third meeting Mr. Lewis Foreman Day read a valuable paper on "The Making of a Stained-glass Window," in which he set himself the task of showing how such windows could best be made. After dealing with the material, the treatment it undergoes, the design and the framework of lead, he came to the conclusion there was no mystery about the old glass, and that as good stained-glass could be made to-day as the Mediæval artist produced. In illustration of the paper, Mr. Day showed examples of old glass, and specimens of the varied colours in modern glass, by projecting the image of the glass itself on the screen.

On March 29 Sir Edward Maunde Thompson, principal librarian of the British Museum, read an important paper on "English Art in Illuminated Manuscripts," which consisted of a masterly review of the history of the illuminated MSS. produced by Englishmen at a time when the pictorial art of the country was almost exclusively confined to this mode of treatment. The paper was illustrated by a series of lantern slides taken from some of the finest Mediæval manuscripts in existence.

Mr. Joseph Pennell, in his paper on "Senefelder and the Centenary of Lithography, 1798-1898," read on May 3, pointed out that we have the inventor's own authority for the assertion that, although experiments on printing from stone had been undertaken in 1796, chemical printing (or lithography as now practised) was not discovered until 1798. Mr. Pennell's paper was illustrated by a series of lantern slides taken from the masterpieces of the art in the Print-room of the British Museum.

The last meeting of the section was on May 10, when Mr. F. S. Ellis read an appreciative paper on the "Life Work of William Morris," in which the different productions of Morris's genius were reviewed. The meeting was held in the afternoon, and a fine collection of objects illustrating Morris's art was shown by daylight. There were two fine tapestries, one of the "Four Seasons," from Morris's own design, lent by the Science and Art Department, and the other a reproduction of Sandro Botticelli's "Primavera," lent by Messrs. Morris & Co.

Six courses of Cantor lectures were given during the session. The first of these was by Dr. Eugene Obach on "Gutta Percha." Dr. Obach is a well-known authority on this subject, and his position as chemist to the important firm of Messrs. Siemens Brothers has given him great experience of the application of gutta percha in telegraphic work and for other purposes. His lectures formed an exhaustive monograph of the subject. It was desirable that the history should be written before all those who had been connected with the introduction of the material into the industry had passed away and been forgotten; and the great mass of historical information which Dr. Obach has collected will certainly make this course of Cantor lectures the standard work of reference for this subject. By the liberality of Messrs. Siemens Bros., who contributed a sum of 150*l.* for the purpose, the Society was enabled to publish these lectures in a very complete form and with much supplementary matter.

Later on in the session the kindred subject of "India-rubber" was treated in two lectures by Dr. Morris. In these lectures the sources of supply of the material were the subjects principally considered. Besides describing the well-known plants from which india-rubber is mainly obtained, Dr. Morris indicated several less known plants from which the gum can be procured, and also described improvements in the method of manufacture which will probably, to some extent, supersede the old-established and crude methods which were well described in the course of lectures by Mr. Thomas Bolas on the subject in 1880.

The second course of Cantor lectures was by Mr. Cyril Davenport on "Decorative Bookbinding." The principal feature of this course was the manner in which it was illustrated by coloured lantern slides prepared by Mr. Davenport himself, mainly from originals in the British Museum. In connection with this course there was arranged a small exhibition of bookbindings.

Mr. Hugh Stannus, to whom the Society is indebted for several interesting courses of lectures on the application of art to industrial purposes, gave a course of four lectures in the early part of the present year on "The Principles of Design in Form."

These were followed by three lectures by Professor Noel Hartley on "The Thermo-Chemistry of the Bessemer Process." A melancholy interest is attached to these lectures, because while they were in actual course of delivery, the death occurred of the distinguished inventor whose work they were intended to commemorate. Professor Hartley has been for a long time engaged on the application of the spectroscope to the Bessemer flame, and this course of lectures included the results of his investigations.

The last course of lectures for the year was delivered by Professor Carus Wilson, late Professor of Electrical Engineering at the McGill University, Montreal, on "Electric Traction." The application of electric power to railways has formed a special object of study to Professor Carus Wilson for some time past, and his lectures embodied the results of considerable original investigation, and will, when published, be found to be of great value to those engineers who are dealing with this rather new and difficult subject.

The Albert medal for this year has been awarded to His Excellency Dr. Robert Bunsen, the veteran professor of chemistry at the University of Heidelberg. Amongst the numerous and important scientific discoveries which have rendered the name of Bunsen famous wherever science is valued, perhaps the most striking is the one in which he was associated with his distinguished colleague, Professor Kirchhoff, viz. spectrum analysis, a discovery which has shed a new and unexpected light on the composition of terrestrial matter, and has enabled us to obtain a distinct knowledge of the chemical composition of sun and stars. The contributions which Bunsen has made in the application of chemistry and physics to the arts and manufactures are of the utmost value, and their importance may be measured by two out of many instances. The Bunsen battery was, until the introduction of the dynamo, the cheapest source of electricity; the Bunsen gas burner, by which a non-luminous, smokeless but highly heated flame is obtained, is now not only indispensable in all laboratory work, but is used for heating purposes in thousands of houses and manufactories, and for illumination, by the incandescent system, in millions of lamps. Beyond these Bunsen's contributions to the sciences of chemistry and physics have been of the highest importance; but, perhaps, the greatest benefit which he has conferred through a long life devoted to the advancement of science has been the influence which he has exerted as a teacher.

The Owen Jones prizes have now been awarded annually since the year 1878. The Council of the Society of Arts are trustees of the sum of 400*l.*, presented to them by the Owen Jones memorial committee, being the balance of subscriptions to the memorial fund, upon condition of their expending the interest thereof in prizes to "students of the Schools of Art who, in actual competition, produce the best designs for household furniture, carpets, wall-papers and hangings, damask, chintzes, &c., regulated by the principles laid down by Owen Jones." The prizes are awarded on the results of the annual competition of the Science and Art Department.

Six prizes were awarded this session, each prize consisting of a bound copy of Owen Jones's "Principles of Design" and a bronze medal.

The list of the successful candidates was given in the *Journal*.

The next award will be made this summer, on the result of the present year's examinations. Six prizes have again been offered for competition.

In 1871 John Stock left 100*l.* Consols to the Society, with the condition that the interest should be applied for the promotion of drawing, sculpture and architecture. From time to time, as the accumulated funds permitted, prizes have been awarded under this head, the last previous award having been made in 1893. A gold medal, or a prize of 20*l.*, was offered for competition among the students of the schools of art at the annual competition of 1897, for "the best original design for an architectural decoration suitable for the interior of a building."

At the request of the Council, the adjudication was made by the examiners of the Science and Art Department, who awarded the prize to Alfred Coumber, of the Goldsmiths' Institute, New Cross.

Since 1889 the Council have placed at the disposal of the Royal Drawing Society for competition among the candidates at its annual examination twelve bronze medals, and, as usual, these medals were awarded for drawings sent in by students to the exhibition held by the Drawing Society held in April last.

The considerable growth in the number of candidates entering the Society's examinations still continues, the number for this year being 7,636, an increase of 717 over last year's number of 6,919. The figures for the past nine years are given in the following table, from which it will be seen that the numbers are now more than three times as great as in the year 1890, and that they have more than doubled in the past six years :—

Year.	No. of Candidates.	No. of Papers Worked.	No. of Centres.	No. of Subjects.
1890	2,315	2,474	79	14
1891	2,460	2,667	78	14
1892	2,928	3,143	96	13
1893	3,702	3,916	109	13
1894	4,106	4,376	131	14
1895	4,777	5,108	146	14
1896	6,111	6,568	197	16
1897	6,919	7,513	221	19
1898	7,636	8,372	243	19

It would be satisfactory if it could also be stated that the candidates generally keep up to the same standard, but this is certainly not the case. There is probably not a very serious difference, but the tendency of recent years has been for the qualifications of candidates to decline, and the average of those entering is distinctly below the average of those who entered a few years ago. The percentage of first-class certificates in 1896 was 10·5, in 1897 it was 8·8, in the present year it is 6·05. The percentage of failures has not altered so regularly. From 1895 to 1897 the percentage of failures decreased from 21 to 19·8, which was a satisfactory sign. For the present year the percentage of failure has increased and is now 26·1. It must not be understood from this that the better class of candidates are of a lower standard than of old, or that there are fewer of them. This is distinctly not so. There appears on the whole to be a slight improvement at the top of the list, not perhaps as regards the quality of the very best candidates, which is not likely to improve, but as regards the numbers of high-class candidates. In working out the average results, however, this slight improvement is entirely counterbalanced by the fact that the large increase of candidates is due in the main to the addition of students of a less educated class.

The rapid increase in numbers is due, as has been previously pointed out, to the fact that the County Councils are now able to dispose of considerable funds for the promotion of technical education, and this, as defined by the Technical Education Act, includes the commercial subjects in which the Society holds examinations. Large numbers of students are encouraged to enter for the examinations, and in many cases have their fees paid for them. The result of this is that while the numbers go up the standard goes down. It is not to be argued that this is wholly a bad sign. The Society's examinations serve two distinct purposes. They are, on the one hand, a test of capacity, and they afford students who have passed them evidence that they are qualified in subjects which may be of service to them in their future careers. But the examinations also serve another purpose. The hope of obtaining a certificate may often act as an inducement to students to study a subject, and though the certificate itself may be of slight value, or even though the students may fail to get a certificate at all, they will have profited by the actual study. It does not, therefore, seem desirable to the Council that because the numbers increase the standard should, *pari passu*, be raised. If the standard were made too high the examinations would no longer be an attraction to the humbler class of students, while it is obvious that if the standard was appreciably lowered the examinations would fail to have any value whatever. Practically, therefore, the standard for each class has been kept at about as nearly as possible the same level as that which the experience of past years proves to be most practically useful, probably, if anything, it has a tendency to rise rather than to fall. But since a large number of less qualified students enter for the examinations, the proportion of those taking first class must of necessity, if the standard is kept up, be smaller, while the numbers of those who fail to pass at all is likely to increase, but not to increase in anything like the same degree as the proportion of first-classes decreases. It may reasonably be anticipated that as the excellent work of the County Councils goes on and produces its natural results, the class of new students who have been brought under examination will be improved, and that the proportion of first-classes will again rise to the former level.

The increase in numbers has been spread over nearly the whole range of the examinations. There has been a falling off in the two musical subjects: for rudiments of music 366 entered, against 402 last year, a decrease of 36; and for harmony 161, against 190, a decrease of 29. In all the other subjects—that is to say, in all the commercial or technical subjects—there has been practically an increase, or at all events no falling off. In précis-writing there is one candidate less than last year—17 against 18. In French also there were 5 fewer, there being 322 against 327, but this deficiency is more than made up for by the increase in elementary French, a subject introduced last year; for this there were 218 candidates, last year there were 191. The total number in French and elementary French together amounts to 540, an increase on the corresponding number last year (518) of 22. German shows an increase of 16, 227 against 211. Elementary German an increase of 49; 110 against 61. Italian shows a small, but a good, proportionate increase of 12; 37 compared with 25 last year. In Spanish there are 92 compared with 85, and in elementary Spanish 41 against 22. Portuguese also shows an increase; 26 against 14. The regular increase in all these modern-language subjects is certainly a satisfactory feature. It is also satisfactory to note that there is a distinct advance in arithmetic, 259, whereas last year there were only 191, an increase of 68. This is a subject which ought to draw larger numbers. Possibly the reason that it does not do so is that there are many other examinations available in it. Arithmetic also suffers from the drawback that it is not scheduled by the Science and Art Department as a technical subject. The same remark is applicable to English, in which also a moderate increase is to be noted. There are 189 candidates this year, an increase of 14 over the 175 last year. Commercial geography also shows an increase from 62 to 120; this is, comparatively, a large addition. The subject of economics has not attracted very many more than last year; there are now 27, there were then 23. The two subjects which, as usual, attracted much the largest numbers are book-keeping and shorthand. Book-keeping shows a large increase; there were 3,730 candidates, an addition of 295 on the 3,435 of last year. In shorthand there was an increase of 232, the numbers being 1,791 and 1,559. It is a matter of regret that no candidates ever enter for the less popular languages—Russian, Danish, Japanese and Chinese—and this fact is a comment upon the absence of facilities in this country, as compared with those in other countries, for education in modern languages. In domestic economy there were 21 more than last year, the numbers being 206 and 185.

FRESCOES IN THE HOUSES OF PARLIAMENT.

THE following memoranda by Professor A. H. Church, stating details of his treatment of various works of art at the Houses of Parliament last year, and containing suggestions for future proceedings, have been sent by him to the Office of Works. The First Commissioner says that the Government and the public are much indebted to Professor Church for the great amount of trouble and skill which he has gratuitously bestowed upon these paintings, and it is proposed to ask him to be kind enough to advise as to the steps to be taken to carry out his further recommendations:—

No further treatment of the wall-paintings in the Palace of Westminster was carried out during 1896, but I considered it advisable, in the autumn of last year, to deal once more with the two large water-glass pictures by Maclise in the Royal Gallery, as well as the five frescoes by Dyce in the Queen's Robing-room. The two annexed memoranda, in continuation of those which I forwarded to you in November 1895, refer to the state and treatment of the above-named wall-paintings. The operations were carried out to my complete satisfaction by Messrs. Redhead & Turner, employés of the firm of Messrs. Shrigley & Hunt, of Lancaster and London. The former of these employés has worked in accordance with my recommendations at intervals for some years, while both of them were similarly employed last year in carrying out my instructions as to the treatment of the important series of wall-paintings by the late Mr. Ford Madox Brown in Manchester Town Hall. The operations lasted from September 28 until November 1. During their course I paid seventeen visits of control and inspection. You will recollect that on July 22 last I addressed a letter to Sir John Taylor, in which I stated that there were four glazed paintings in the Peers and Commons' corridors which needed attention. They had become disfigured, since they came under my more particular observation, through the formation of dark stains or through efflorescence and scaling. The pictures referred to are

these :—"The Burial of Charles I.," "Charles I. Erecting his Standard at Nottingham," "The Parting of Lord and Lady Russell," "The Last Sleep of Argyll."

You were good enough, in a communication dated July 28, 1897, to approve of my proposal. But there proved to be practical difficulties in removing and replacing the glasses of these paintings, so that their treatment, expedient as I still believe it to be, has been deferred. In my letter of July 22 I also made mention of an apparatus then being constructed to my order for producing a powerful air-jet, charged with breadcrumbs, to be employed in the cleansing of the Westminster paintings. This apparatus, consisting of a manual air-compressor, a receiver with pressure gauge, and a breadcrumb distributor, was delivered in the Royal Gallery at the end of September. It had to be returned to the makers for some alterations, but did not ultimately prove efficient for the purpose in view. I still hope that, after further modifications, I may be able to bring it into use on a future occasion.

In conclusion, I beg to recommend that during the summer of 1889 the frescoes in the House of Peers should once again be cleansed under my supervision, and that the four glazed corridor paintings already mentioned should be so treated as to remove all their present difigurements, such as the grey film on all of them, and the numerous dark circular patches, possibly of fungoid origin, which are increasing on various parts of the surface of one of the pictures.

The Royal Gallery.—As my previous memorandum concerning the two water-glass paintings by Maclise gives an outline of their history and condition, and of their treatment under my supervision in the autumn of 1894, it is unnecessary to repeat here the details already furnished (in the Parliamentary Paper C. 7,651, 1895). I formerly stated that it would probably be advisable to protect the surface of these wall-paintings with a preservative solution containing as its chief ingredient hard paraffin wax. I waited until the present year before venturing to carry out this plan, being anxious to ascertain previously whether efflorescence took place after the cleansing operations conducted three years ago. However, so little change of any kind had occurred since 1894 that I felt confident that the suggested application might be safely made. It was of course necessary first of all to clean once more the surface from accumulated dust and soot. This having been accomplished by an air blast, careful dusting and the use of bread, the paraffin wax (dissolved in toluol to which had been added a small quantity of a specially-prepared copal-varnish free from lead) was applied. Some parts of both pictures, being more tender and absorbent than the rest of the surface, were treated several times, indeed until suction had practically ceased. Not only was the improvement thus effected in the definition and general appearance of the paintings very decided, but there is good reason to conclude that the injurious action upon these works of the impure London atmosphere, and of the occasional condensation thereon of corrosive moisture, will be considerably lessened in the future. It will be necessary to repeat the cleansing operations at regular intervals, say every third or fourth year. And it may be expedient to apply the paraffin-wax solution once again, especially over areas where weakness of the ground or of the pigments has been observed. This further treatment is the more desirable because of the loose condition (pointed out in Memorandum I.) of much of the blue pigment and of some of the dark red in the "Nelson" stereochrome. For the same quantity of paraffin-wax applied during the past season to this painting is not likely to suffice for the consolidation and for the attachment to the ground of these peculiarly powdery pigments.

The Queen's Robing-room.—The history, condition and treatment of the five true frescoes in this room were fully discussed in Memorandum III. During the three years which have passed since they were last cleaned and treated with paraffin-wax they have hardly deteriorated at all. The surface was cleansed with bread, a few necessary but quite insignificant touches were given, and the same preservative solution as before was applied, the application being repeated twice or thrice on those places where the ground or the pigment was friable. With reference to the future treatment of the paintings, I recommend that they should be cleansed, and if necessary paraffined, at intervals of three or four years. I believe that by continued care and attention they may be maintained for a long time pretty nearly in their present condition.

The Annual Congress of archæological societies was held at Burlington House on Wednesday. The principal subject for consideration was the preservation of ancient monuments. It was pointed out that in the Blue-book containing an account of what was done in foreign countries, Russia alone resembled England in the absence of any provision for securing remains from injury. After some discussion it was decided to enter into correspondence with the various county councils, inviting their co-operation to insure safety for ancient buildings.

TESSERÆ.

The Portrait Statues of Buddha.

THE great pioneer of our Indian researches, Sir William Jones, pronounces unhesitatingly that Buddha, in the opinion of his worshippers, was a negro; M. Langlés is peremptory on the subject of his African origin, and a host of lesser names, such as that of Moor, the author of the "Hindoo Pantheon," are arrayed on the same side of the question. On the other hand, Remusat has collected abundant evidence to prove that the descriptions of the person of Buddha in the Buddhist books refer to an Asiatic, and that his titles and epithets, as applied to a negro, would be in the highest degree ludicrous. In Davy's "Description of Ceylon" there are arguments on the same side by a practical man, and Guigniaud dismisses the subject in a short note as incontestably proved against Sir W. Jones. The statues of Buddha are the principal, if not the only witnesses in this dispute, and they are appealed to by both sides. In the first place, these images are sometimes represented black, but as the images of Vishnu and Krishna are so also, this proves nothing more than that black is a symbolical colour among the Hindoos. "Such representations," says Mr. Upham, "have not only the hair, but the thick lips and the features of an African negro." The statues Mr. Upham alludes to have, it is true, thick lips, but they are not the thick lips of an African negro, and as for the other parts of the face, we cannot well imagine anything more dissimilar to negro features. The hair of a negro is matted and crisp, like the wool on the back of a sheep, while that of the Buddhaic statues is divided with the nicest regularity into small curls. Nevertheless, it is impossible to deny that the colour and compact appearance of the latter suggest very forcibly the idea of the former. The Buddhists very naturally evince some uneasiness when their idol's hair comes in question. They cannot deny that it presents a different appearance from the living Asiatic locks with which it may be compared, and the stories they invent to account for a phenomenon of which the tradition is lost are not a little absurd. In one of them the mystery is solved by the fact of their sage having had his hair cut with a golden sword. The Jains, according to Major Mackenzie, account for the negro heads of their statutes by affirming that their ascetics being forbidden the use of the razor employ their disciples to pluck up the hair by the roots. This curious explanation is received in triumph by Remusat, who thus contrives to expose the blindness of prejudice in himself and his opponents at the same time. In the superb statue of Buddha in the cave of Gharipuri (Elephanta), Moor tells us a large rose projects on each side of the head, as if confining the hair. The same author is confident that the hair is woolly, and affirms that the appearance is seen in no other Hindoo deity, but when we turn to the plates he has himself given us in the Hindoo Pantheon, we find that the latter assertion was very incautiously made. Some authors attempt to solve the problem by remarking that Ethiopia may have been one of the countries which produced a Buddha, or into which the Buddhaic religion was introduced at some early period, and that his Ethiopian statues introduced into India in the infancy of art may have been blindly copied by succeeding generations. Crawfurd's account of Burmese statuary is perhaps equally applicable to the art in the whole of the Buddhist countries. "The Burmese statues are as rudely finished as possible. They are almost all in the same attitude; the form and position of the limbs are the same; the head and features are the same, and there is no room in any respect for the display of taste, fancy or talent, the whole operation being purely mechanical, and this of the lowest order."

Sir W. Chambers and Horace Walpole.

A design for Lord Clive's villa at Claremont, in Surrey, was made by Sir William Chambers, but that of Brown, the landscape gardener, was preferred, and this occasioned a difference between the two artists which was never entirely reconciled. The learned and travelled Chambers considered the unlearned and untravelled Brown as an ignorant intruder—one whose mean education rendered him an unworthy antagonist to a knight of the Polar Star; and who, moreover, made light of the mystery of Oriental gardening, and was therefore entitled to no respect. Upon this he wrote and published in 1772 his "Dissertation on Oriental Gardening," and in the introduction handled Capability Brown, as he was generally called, with little delicacy or deference. Of the numberless satires which the dissertation called into life, the only one, however, which survives is the "Heroic Epistle," attributed for a time to Anstey, the author of the Bath Guide, but now known to be the work of Horace Walpole, with some aid from Mason the poet. When Warton was pressed in conversation to say what he knew about it, and whether it were or were not Mason's, he replied, "Aye, sir, cut out by Walpole, but buckramed by Mason." Lord Orford, secure as he imagined in concealment, thus wrote of the work of Sir William and his own epistle in 1784 :—"The great improvement suggested by Chambers was

the abolition of geometrical lines and curves, and the contrary extremes of bareness, trimness and serpentine walks, by which an equally disgusting monotony was produced. His remedy was to introduce an infinite variety of artificial embellishment, and thereby to effect continued surprise by objects totally new to the English eye, somewhat familiarised to Grecian forms. But the triumph of Chambers was of short duration; no sooner had the 'Heroic Epistle' followed so closely upon his dissertation than the national taste recovered from its aberration—the wit and irony delighted—the delicate satire was universally relished, pointed as it was by political allusions. The gardens of Kien-Long transplanted into England were made to contain the court, and so concluded the Chinese controversy." Chambers's crime, in the eyes of Walpole, was no less than using his elaborate work as a weapon to deter the king from introducing classic improvements into the gardens of Richmond. The main doctrines of the dissertation had, however, been made public some years before the English Garden of Mason appeared, and there is no better foundation than surmise for the suspicion of Walpole. It must be acknowledged that the lofty and cumbrous language of Sir William's dissertation is imitated with much skill in the Epistle, and that the poet has aptly caparisoned his rhyme from the turgid sentences of the architect. "In their lofty woods," says Chambers, "serpents and lizards of many beautiful sorts crawl upon the ground, and innumerable monkeys, cats and parrots clamber upon the trees. In their lakes are many islands, some small, some large, amongst which are seen stalking along the elephant, the rhinoceros, the dromedary, the ostrich and the giant baboon. They keep in these enchanted scenes a surprising variety of monstrous birds, reptiles and animals, which are tamed by art, and guarded by enormous dogs of Tibet and African giants in the habits of magicians. Sometimes in this romantic excursion the passenger finds himself in extensive recesses, surrounded with arbours of jessamine, vines and roses, where beauteous Tartarean damsels, in loose transparent robes that flutter in the air, present him with rich wines and invite him to taste the sweets of retirement on Persian carpets and beds of Camusakin down."

The House of R. Cosway, R.A.

In his anecdotes relative to Cosway, Nollekens's biographer says that, after quitting Pall Mall, "he (Cosway) fitted up his new residence (No. 20 Stratford Place) in so picturesque and indeed so princely a style, that I regret drawings were not made of the general appearance of each apartment, for many of the rooms were more like scenes of enchantment pencilled by a poet's fancy than any thing, perhaps, before displayed in a domestic habitation." If such really was the case, they certainly were worthy of being delineated, yet we may be allowed to entertain some misgivings—first, because such a character of the house partakes too much of the "glamour might" of some of George Robins's advertisements; and, secondly, nothing is said to corroborate it, or to give us any idea whatever of those "scenes of enchantment," notwithstanding that the writer could at least have done that, have spoken of "the general appearance of each apartment," and have so far rescued them from complete oblivion. Instead of which, he merely goes on to astound us by enumerating some of the costly articles of furniture and *vertu* which were displayed in the habitation of that once fashionable and now forgotten painter; to wit, "ancient chairs, couches and conversation stools elaborately carved and gilt, and covered with the most costly Genoa velvets; escritoires of ebony inlaid with mother-of-pearl, rich caskets for antique gems exquisitely enamelled and adorned with onyxes, opals, rubies and emeralds. There were also cabinets of ivory curiously wrought, mosaic tables set with jasper, bloodstone and lapis-lazuli." Suffice it to say that there were besides, among a variety of other things, "massive musical clocks, ottomans superbly damasked, Persian carpets, chimneypieces carved by Banks, bronzes, models in wax and terra-cotta, crystal cups adorned with the York and Lancaster roses, &c., &c." To meet with such prodigal sumptuousness in the house of a painter must have been astonishing enough—almost incredible when contrasted with the scrubby, though never scrubbed, dog-hole rooms in which old "Nolly" and his amiable spouse thrived so well; or the wretched but richly cobwebbed garret in which Barry entertained Burke with a beefsteak and a pot of porter. Still, one is at a loss to make out, from all that Smith says of Cosway's house, aught that warrants the expression of the rooms being so many scenes of enchantment, there being not a syllable even with regard to any of their decorations, or to indicate any particular fancy or *recherché* taste, or well-studied effects in the rooms themselves. Sumptuous furniture and almost priceless works of art may be put into a very commonplace room, but in such case the latter is merely the receptacle of the other objects, stripped of which it would not be worth looking at, whereas—in a first-rate mansion, at least—every part of it, except the entirely private and domestic rooms, should be laid out with studied regard to effect and to variety of effects—without, however, departing from consistency as to general character. Each apartment should be itself a picture—strikingly beautiful in itself, charming, captivating, before it receives its finishing touches in the way of furniture and other accessories.

GENERAL.

The Pont Alexandre III., now in course of erection over the Seine, will be adorned with sculpture on a large scale. The four lions at the extremities will be the work of MM. Dalou and Gardet. M. Freimet will model two winged horses, and commissions are held by MM. Coutant, Cordonnier and Récipon.

Ashton Hall, Liverpool, which has been altered into a school of hygiene in connection with University College, was opened on Monday. The laboratory is well equipped for investigation of sanitary problems.

Viscount Peel was on Tuesday elected a Trustee of the British Museum in succession to the late Mr. Spencer Horatio Walpole.

The Report of the Select Committee on Museums is expected to recommend that a school of science and art with a library should be formed in connection with the Bethnal Green Museum, as originally contemplated.

The Duke of Devonshire has presented to Eastbourne a site for a technical institute and public library as a memorial of his mayoralty.

Mr. E. A. Abbey has been elected a Royal Academician. He is the third American possessing the privilege. Mr. Abbey has been only a few years in England, and was at first known by his illustrations of books and periodicals.

An Interesting archæological discovery has just been made at Tongres, province of Hasselt, Belgium, where excavations in one of the tumuli at the intersection of two Roman roads have brought to light a sarcophagus containing the remains of a Roman artist of the third century. With the remains were found a large number of urns, vases and miscellaneous trinkets; but perhaps the most interesting item were the bronze cups containing remains of the artist's colours, which will, it is hoped, throw some light on the process of contemporary painting.

Chantilly is to be opened for three months on Saturdays at a charge of 1 franc, the proceeds to be given to the Society for the Relief of the Wounded. On Sundays and Thursdays admission will be free.

A Meeting of friends and admirers of the late Sir Edward Burne-Jones was held at Dorchester House on the 4th inst., when it was resolved to raise a fund to be applied to the purchase of a characteristic work by him, to be presented to the nation as a memorial. The sum required will be from 3,000*l.* to 5,000*l.*

A Special General Meeting of the Architects' Benevolent Society will be held in the rooms of the Royal Institute of British Architects on Wednesday, July 13, to confirm the resolution passed at the annual general meeting held on March 9, 1898, to the effect that the words "six pensions of not less than 20*l.* each" be substituted for "three pensions of not less than 15*l.* each" in By-law No. 65.

The Annual Exhibition of handwork of the pupils of the School Board for London will be held at the Hugh Myddelton School, St. James's Walk, Clerkenwell Green, E.C., from Friday, the 15th inst., until the following Wednesday. It will be open each day from 12 o'clock noon until 8.30 P.M. The exhibits will include specimens of the following work:—Drawing, painting in water-colours, designing in paper and colour, modelling in clay and cardboard, manual training (woodwork), wood-carving, metalwork, kindergarten, &c dress cutting and making, and needlework from evening continuation schools, and special exhibits from schools for the deaf, schools for the blind, and schools for the instruction of physically and mentally defective children.

A Chapel for the Welsh Calvinistic Methodists is being erected in Suffolk Street, Birmingham, and the memorial-stones were laid on Wednesday. The new building is well set back from the road, and when finished will be 30 feet wide by 47 feet long, giving accommodation for rather over two hundred people. In addition there is to be a meeting-room and a house in the rear. Its cost, it is estimated, will amount to about 4,000*l.*, including 1,412*l.* 18*s.* 11*d.* for the purchase of the land.

The National Trust for Places of Historic Interest o Natural Beauty, of which the Duke of Westminster is president, is, it is stated, in the field for the purchase of Tintern Abbey. It is suggested that a number of local gentlemen should purchase the abbey and Monmouth and Raglan castles, pending the promotion of a Bill in Parliament enabling the Monmouth County Council to acquire these historic buildings.

THE

Architect and Contract Reporter.

IMPORTANT NOTICE.

WORKMEN'S COMPENSATION ACT.

In view of the many difficulties which are certain to arise in connection with the law, practice rules and procedure under the above Act, we have added to our staff A VERY EMINENT BARRISTER, who has made the subject a special study, and will be glad to answer in the columns of this paper any questions relating to the complicated matters arising from the provisions of this difficult Act. Our LEGAL ADVISER will further answer any legal question that may be of interest to our readers. All letters must be addressed "LEGAL ADVISER," Office of "The Architect," 175 Strand, London, W.C.

COMPETITIONS OPEN.

BUILDING AND BUILDERS.

A NEW parsonage house is being erected in the parish of Bollington, Manchester.

TENDERS amounting to 7,818*l.* have been accepted for the erection of the new Wesleyan college on the Weaponness Estate, Scarborough, and the first sod will be cut at Conference by the President.

A WORKING agreement has been signed on behalf of the Master Masons' Association of Glasgow and Neighbourhood and the Glasgow and suburban lodges of the Operative Masons' Association of Scotland regulating the rate of wages and conditions of labour for the next twelve months. The most important point in the agreement is the raising of the standard rate of wages from 9*d.* to 9½*d.* per hour.

THE foundation-stones were laid on the 2nd inst. of a Free Methodist chapel at Alderman's Green, near Coventry. The new building is to supersede one erected about forty years ago. It will be of red brick, relieved by Bath stone dressings, and will accommodate some 320 persons. The cost will be upwards of 1,000*l.*

AT the hospitals committee of the Liverpool Corporation there was read a letter from the assistant-secretary, Local Government Board, stating that the Board were willing to sanction the borrowing of 38,000*l.* for the purchase of a site for the proposed infectious hospital at Fazakerly on certain conditions. There was also read the report of the medical officer. The report was approved, and the town clerk is to inform the Board that the conditions stated in their letter will be carried out.

A SPECIAL meeting of the Pateley Bridge Rural District Council was held on the 2nd inst. for the purpose of considering the question of an isolation hospital for the district. Mr. Harker, C.C., chairman of the Council, reported upon a combined meeting held at Harrogate for the consideration of the question. Dr. Kay, medical officer for the West Riding Council, was present, and gave several particulars as to cost, &c., of a separate and also of a combined hospital. Dr. Lumsden, the local medical officer, was also present. After some discussion the Council decided to join the Knaresborough and Harrogate districts in providing a joint hospital for the three districts.

ABOUT 350 men and boys employed at the terra-cotta and brickworks of Messrs. Gibbs & Canning, Limited, Glascote, Tamworth, are on strike. The men belong to the National Union of Gasworkers and General Labourers. Taking the various sections of work, for which different rates are paid, it is stated that the increase demanded averages 7½ per cent., and that the firm made small advances in certain departments before work ceased, but that the men are holding out chiefly to secure an increase in the wages of labourers. The firm has intimated that the conditions of trade prevent them from granting any further concessions in wages. At the works during the latter part of last week clerks, managers and other officials loaded up several orders for despatch by rail.

THE threatened strike in the Paisley building trade, which was expected to have commenced last week, was avoided by the

master builders of the town granting the demands put forward by the workmen. The men had asked for an increase of wages from 9*d.* to 9½*d.* per hour, and also a stipulation from the masters that they would not change the present agreement, which allows not more than six apprentices in their service. On this latter point—the question of apprentices—the masters had been anxious to have the number allowed increased from six to nine, but owing to the present briskness of the building trade, they have had to concede both demands put forward by the workmen. The arrangement now come to is to be effective for a year.

The Labour Department of the Board of Trade has sent a communication to Bristol appointing Mr. A. A. Hudson, Q.C., of the Temple, London, as arbitrator in the Bristol building dispute. At present several hundred plasterers and masons are on strike, demanding a halfpenny per hour advance in their wages, and many labourers are temporarily thrown out of employment. Mr. Hudson will sit next week at a conference of representatives of employers and employed, and various points will be submitted to him for settlement.

The North-Eastern Railway Company contemplate an important addition to their Hull property by the erection of an engine-shed and other offices. Accommodation is to be provided for forty-eight engines, and the floor space required will be about equal to the present passenger station in the city. This has turned public attention to the project, now discussed for many months, for the enlargement and improvement of Paragon station. For some time past the company have been buying large areas in Collier Street and the neighbourhood adjacent to the station. On these areas there stand many tenements, the great majority of which are in a dilapidated and tumble-down condition, and quite unfit for human habitation. The sanitary authority of the city are therefore equally as anxious as the travelling public for the improvement, for areas will be cleared which at the present time are a disgrace to any civilised community. In making arrangements for the building of a new engine-shed, the company are inspiring a general belief that the proposed works are but the immediate prelude to a scheme for a new station which, when completed, will be worthy of the size and rank of Hull, as one of the chief ports of Great Britain.

The foundation-stone of a parish church which is in course of erection at Newport (Mon.) was laid on the 30th ult. The new church of St. John the Baptist is for the parish of that name, which has just been formed. It is situated in the Risca Road, and will accommodate about 700 persons. The present contract, which has been taken by Mr. W. A. Linton, of Chepstow Road, Newport, is for the erection of the nave, north and south aisle, south porch, chancel, south chancel aisle, north chancel aisle as an organ chamber, a sacristy on the same floor as the church, and a large vestry, a store and heating chamber in the basement, with stairs leading up to the north chancel aisle. This will complete the church, with the exception of the west tower, which is contemplated, but the designs for this have not been elaborated yet. The style of work is of the Devon and Western Counties type of Late Gothic. The material is red Risca walling with Bath stone dressings. The floors for the most part are to be of wood block, but the chancel floor will be in mosaic. The roof will be covered with grey slate. The design is intended to be greatly enriched as regards the interior from time to time as funds will allow. It is hoped that the screen, the altar-pieces, the pulpit and chancel fittings will eventually be of elaborate woodwork, and that many of the windows may be filled with painted glass of the best description, a scheme having been proposed for the treatment of every window in the church, so that there may be a proper fitness in the whole conception and treatment. The designs are by Mr. F. R. Kempson, of Cardiff and Hereford.

In Glasgow Sheriff Court Frank M'Fadyen, mason's labourer, residing at 17 Brown Street, sued James Stevenson, brickbuilder, 3 Hamilton Road, Rutherglen, claiming compensation for injuries which he sustained on September 27. Plaintiff on that date was in the employment of Messrs. M'Kay & Gray, builders, when a brick partition wall on the fourth storey of a tenement in course of erection at Barrington Drive fell upon him. Defendant was the contractor for the brickwork of the tenement, and Sheriff Strachan, holding that he was responsible for the accident, awarded the plaintiff 25*l.* and expenses. The Sheriff said that such a wall would not have fallen if it had been built with ordinary skill or care. The work was executed by two young lads, one in the fifth and the other in the third year of his apprenticeship, without the superintendence of a foreman or skilled workman.

The memorial-stone of Queen's Cross Free Church, Glasgow, which is at present in course of erection in the mission district in connection with Free St. Matthew's Church, was laid on the 22nd ult. The church, which is situated at the

corner of Garscube Road and Springbank Street, is being built from designs prepared by Messrs. Honeyman & Keppie, architects. The style is a free treatment of Late Gothic, and the work is of a substantial character. The principal feature of the building is a tower of robust proportions, placed at the corner of the two streets. This is flanked in the Garscube Road by the transept gable, and in Springbank Street by the window of the choir chamber, which is placed at a high level. The building will provide accommodation for 790 sitters, and a choir of 30 members. The interior is so arranged as to give an uninterrupted view of the pulpit, which is placed at one side. The passage from the main entrance from Garscube Road runs along a narrow aisle, from the inside piers of which the roof principals spring. There is a transept and back gallery, and behind and at the side of the pulpit are the organ chamber and seats for the choir. At the back of the church is a hall seated for 260 persons. The site of the church cost 1,880*l.*, and the estimated cost of the buildings is 6,300*l.*, which, with architects' fees, &c., will be increased to about 7,000*l.*, making an estimated total cost for site and buildings of about 8,900*l.* sterling.

TRADE NOTES.

WE are informed that the Yost typewriter has been awarded a gold medal at the Agricultural Show held at Pretoria, South Africa, in April last. This makes a total of eighteen gold medals awarded to this machine—quite a record in the typewriter business.

IN the ventilation of the Paisley Parish Council Halls (Mr. T. G. Abercrombie, architect), Cousland's "Improved Climax" continuous exhaust patent direct-acting ventilators have been used, supplied by the Climax Ventilating and Heating Company, 93 Hope Street, Glasgow.

THE NATIONAL PROVINCIAL BANK OF ENGLAND, PICCADILLY.

ELECTRIC NOTES.

AN important meeting of the Stockport electric-lighting committee was held last week. It was reported that the public supply for street lighting would be available at the beginning of November, and that tradesmen would also be supplied then under specially advantageous arrangements. The committee will also cater specially for the adoption of electric power in manufacturing processes. The inauguration of an electric tramway system is under consideration, and if carried out will be immensely popular.

SCHEMES for electric tramways between London and Oxford and London and Brighton are shortly to be submitted to the Light Railway Commissioners.

AT a recent meeting of the gas committee of Dundee Town Council, a report was submitted by the electrical engineer with regard to the proposed extension of the electric lighting area of the city. After consideration, the committee agreed to recommend the erection of twenty-seven lamps, at an estimated cost of 838*l.* 17*s.*, the running cost being 550*l.* per annum.

ON the representation of the resident engineer, the electric lighting committee of the Edinburgh Town Council have recommended an extension of the low-tension continuous current mains to Balcarres Street, the usual guarantee being given. The probable cost is 1,600*l.* It has also been agreed to recommend acceptance of an offer for new offices, stores and other buildings at the Corporation's electric lighting station in Dewar Place, amounting to somewhat over 6,000*l.*

THE electric light and traction committee of St. Helens, Lancashire, have decided to lay out the Boundary Road site so as to concentrate the whole of the plant both for lighting and traction purposes there. It has been further decided, in view of the possible lighting of Church Street, Bridge Street, Liverpool Road, Cropper's Hill, Westfield Street Cotham Street, Corporation Street, Duke Street and Shaw Street by means of arc lamps, that finials be put on every second or third trolley pole in those streets.

THE North Berwick Gas Commissioners had under consideration at their monthly meeting on Monday evening a report from Messrs. Burstall & Monkhouse, Westminster, in regard to the proposed introduction of the electric light into the town. The report showed that it would be unsuitable to put down the electric-lighting station at the present gasworks, and dealt with the extra capital and annual cost of placing it at the

PRICES AND PARTICULARS ON APPLICATION TO

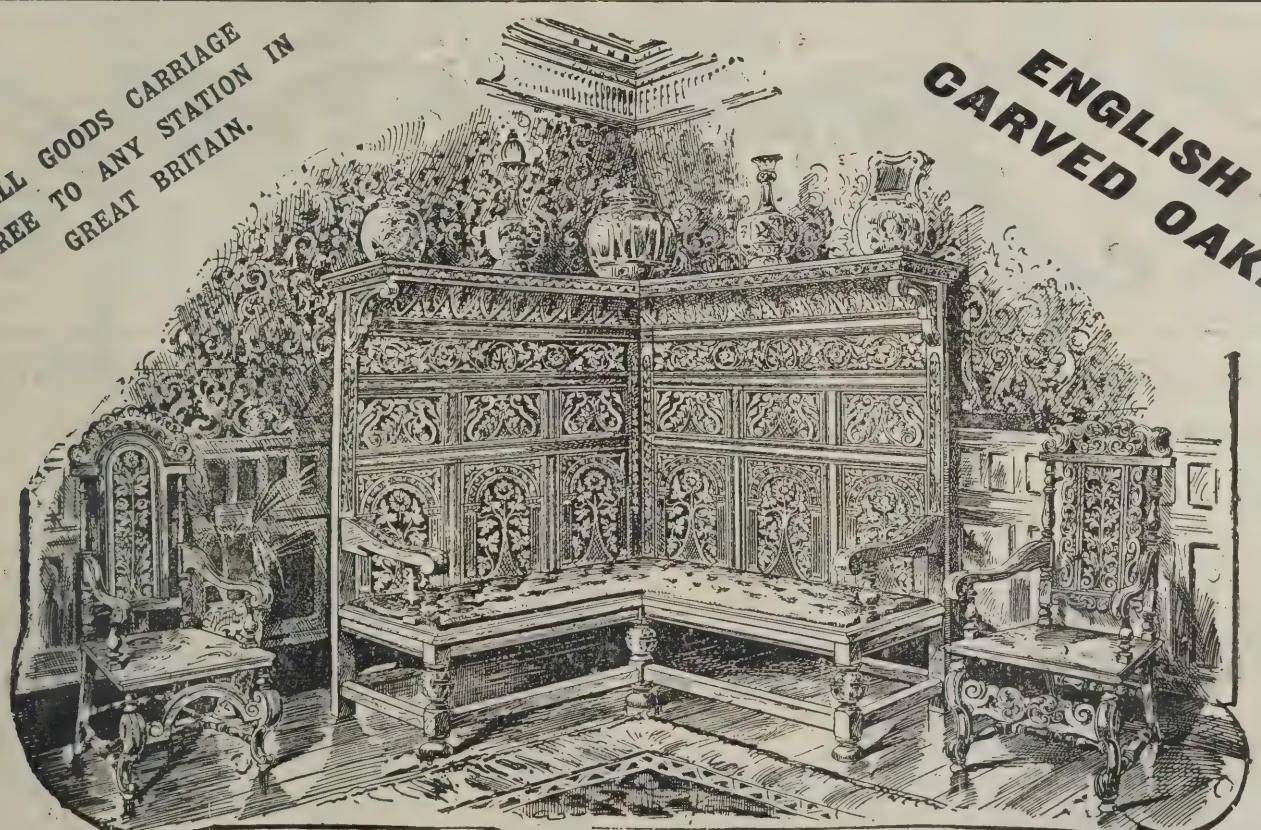
THE UNITEDASBESTOS CO., LTD., 158-160 CHARING CROSS ROAD, W.C.

Chief Offices—Dock House, Billiter Street, E.C. Also at Manchester, Newcastle, Liverpool, Hull, Cardiff, Glasgow, Bristol, &c., &c.

site proposed for the new gasworks, and with other details of the scheme. The system proposed is the low-tension current one. The capital cost is estimated at 7,600*l.* It was resolved that the Board have an early special meeting to discuss the matter.

A SPECIAL meeting of Kirkcaldy Town Council was held on Tuesday night to consider the electric-light and tramway scheme for the burgh. A letter was read from the Edison Light Company, intimating their intention to apply for an order to put down electric-light plant for Kirkcaldy. The Provost explained that the question for them to decide was whether or not the Council should take up the scheme. He felt warranted in saying that the scheme as prepared by Professor Kennedy would pay, and he was in favour of the Council taking up the matter. The meeting agreed to remit the matter back to the joint committees to consider, and report to the September meeting.

FOR years the advisability of introducing electric light into Runcorn has been mentioned, but the District Council have taken no steps to obtain the necessary powers. Their hands have now been forced. The Electrical Power Distribution Company, London, have notified their intention to apply to the Board of Trade for a provisional order to supply electricity in the district. The Council, believing such power should be vested in the Council, have decided to make a similar application in opposition.



A SPECIAL meeting of the Tipton District Council was held on the 24th ult. to further consider the question of giving their consent to the application by the Midland Electric Corporation for Power Distribution, Limited, to the Board of Trade for a provisional order to supply electricity within the Tipton district; Mr. C. H. Burrows presided. Mr. Parrish (solicitor) submitted a draft agreement which would be entered into if the Council decided to withdraw their objection to the Bill. He pointed out that under the agreement the maximum price for the supply of electricity for lighting in bulk would be 3*d.* per Board of Trade unit, and the Council would have the option of appealing to an arbitrator twelve months after the passing of the Act to determine whether or not this was a fair price. The price was also subject to revision every seven years. Mr. Doughty said he was still of opinion that the price should not exceed 2*d.* per unit, and the question was whether they should resort to arbitration at the outset to determine the point. Mr. Lowe (solicitor to the Corporation) said the Company would supply the meters to individual consumers, and would accept the Council's reading of them for the basis of their charge. The chairman pointed out that the Council would be empowered to charge 6*d.* per unit for the first hour, and this would be the only means by which they would be able to make a profit, after meeting the expenses incidental to obtaining the readings of the meters, &c. After some further discussion, the Council decided to adopt the agreement, and withdraw their opposition to the Corporation's application.

INFORMATION has been received by the Leamington Corporation that the Board of Trade will not proceed this year with the electric-lighting order which the Corporation has been endeavouring to obtain. It is expected that an official communication on the subject will be received in a few days. In the meantime it is understood that the delay is owing to the unwillingness of the Board of Trade to deal with the Leamington order until certain points have been decided in two other orders which have already passed their second reading in the House of Commons, but have still to be dealt with in committee. It is stated that on the ultimate decision of the House on these points will depend the Board of Trade's action in regard to similar questions in the Leamington order. It will not, however, now be possible for the Corporation to take further active steps in the matter until next session. It is expected that then the Midland Electric-lighting Company, who are at present supplying electricity in the borough of Leamington under an agreement with the Corporation, will also seek to obtain a provisional order.

AT Morley, Yorks, on the 24th ult., the opening of the Corporation's newly completed electricity works was a function of considerable local interest, attended by all the leading residents. The generating works are situate in Corporation Street, between the new public baths and the Corporation depôt. The buildings, which were designed by the late borough surveyor (Mr. M. H. Sykes), are placed on the south side of the land reserved for the generating works, and are so arranged that a considerable area of land is reserved for future extensions. The total area of the site consists of 4,132 square yards. The engine-house is 40 feet wide by 38 feet long, with switch-room at one end. At a height of 20 feet an overhead travelling crane runs along steel rails the full length of the engine-house. The test-room is conveniently situated at the east side of the switch-room, the floors of which rooms are laid with wood block flooring. The accumulator-room, 40 feet by 12 feet 6 inches, is

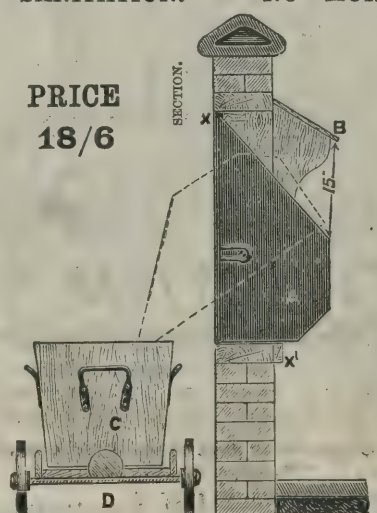
placed over the switch-room and test-room, and is approached by a staircase near the main entrance. The boiler-house is placed parallel with the engine-house on the west side thereof and is 68 feet long by 48 feet wide. Along the west side of the boiler-house are placed the coal bunkers, 10 feet wide, and the pump-room, 10 feet by 12 feet. At present there are two Lancashire boilers, 30 feet by 8 feet diameter, and accommodation is provided for other two of equal size. The offices are situated over the work and store-rooms, and are approached by two staircases, one being from the main entrance-hall and the other being a spiral staircase from the boiler-house to the chief engineer's private office.

VARIETIES.

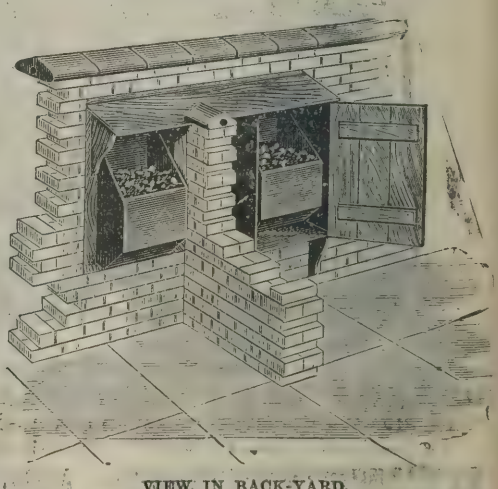
A NEW Roman Catholic church at Oswaldtwistle, dedicated to St. Mary, is now open.

A NEW railway station has been erected at Felixstowe by the Great Eastern Railway Company at a total cost of about 33,000*l.*, and has now been opened for the purposes of public traffic. The building was designed by Mr. John Wilson, the company's chief engineer. It stands upon a conveniently central site, beside an extension of the Victoria Parade, which forms the principal business thoroughfare of this rising seaside resort, and the accommodation provided will doubtless be sufficient for a good many years to come. The "circulating area" beyond the booking offices is 92 feet long and 84 feet broad; the main platform is 785 feet long, 500 feet being roofed over with glass, and there is a second platform 650 feet in length.

THE greatly enlarged and renovated Roman Catholic parish church of Bray, Ireland, is now so far completed as to be ready for the opening service, which is to take place on Sunday next, and it is not too much to say that the new building is an acceptable addition to the architectural features of Bray. The dimensions of the new portion are, in length, 104 feet from back of wall of apse to the point of contact with the old portion (which latter measures 50 feet, making the entire length over 150 feet); width across the transepts, 90 feet, and across the nave, 45 feet; external height to cresting of roof, 72 feet, and that of the interior to centre of panelled ceiling, 54 feet. The depth of apse is 27 feet and its height 48 feet, while the baldachino over the high altar reaches an altitude of 32 feet. The style is Late Romanesque; the windows and arches are rounded, the carving of capitals, corbels and cornices tends rather to the ornate Gothic period and the heavier lines of the strict Romanesque are thus agreeably toned down considerably. The architect is Mr. W. H. Byrne. A new roof has been put on and a new ceiling inserted. The church is now very nearly finished in all its details, and by the day of the opening ceremony it is confidently expected that everything will be completed.



MUCH interest has been excited in Leicester by the discovery of two additional tesselated Roman pavements in one of the most ancient quarters of the borough. They were laid bare at a depth of about 8 feet. One measures 13 feet by 10 feet and the other 12 feet by 7, and both are in a remarkable state of preservation. They are of really beautiful design, and in this respect resemble others which had been previously discovered. In the larger portion there is the representation of a peacock with spread tail. It is known that the old Roman forum stood here, and it is accordingly believed that the pavements originally belonged to the Governor's residence or to the temple of Janus, which was situated in the same neighbourhood. The newly-discovered pavements will be preserved intact in the position in which they have been found.



A NEW Baptist chapel was opened at Redditch on Wednesday. The building is of the Early Gothic style, of red brick with white stone dressings. It is 60 feet long, 36 feet 6 inches wide inside and 40 feet wide across the transepts, and seating accommodation is provided for 630 persons, with room for adding 130 sittings. There is an ornamental tower about 60 feet high. The plans for the church and schools—the latter, though detached, harmonising with the former—were prepared by Mr. John Wills, F.S.Sc., of London and Derby, and the work was done by Messrs. C. G. Huins & Sons of Redditch. The original estimate of the cost was 3,546*l.*, but 800*l.* has since been added.

ON Saturday last Lady Overtoun opened the new Bonhill Bridge, which replaces the old suspension bridge on the same site, the dangerous position of which led to the design of the structure now completed. The new bridge has one span of 169 feet, with a width of 35 feet, divided into a roadway of 21 feet, with a footway on either side of 7 feet. The type selected, viz. a girder bridge, was necessitated by the existence of a towing path which could not be interfered with, and which precluded the possibility of employing an arched structure. The bridge is of the bowstring girder type, and has a curved upper member connected to the lower member by a series of diagonal bracing; and to augment the headway as much as possible the bottoms boom, instead of being truly horizontal,

was given a "camber" or arch of 3 feet. A light lattice screen girder fastened to the main girders on either side, and surmounted by a teak cope, forms the parapet. The abutments are of red sandstone, with granite blocks under the ends of the girders, and massive pilasters, with ornamental mouldings and corbels, are erected at each end of the structure. The bridge, which has cost about 7,000*l.*, was designed by Messrs. Crouch & Hogg, Glasgow.

THE plain old Wesleyan chapel in Oxford Place, Leeds, is being greatly modernised and improved, and the Sunday schools in connection therewith have been rebuilt. The latter, which are from the designs of Messrs. Danby & Thorp, Leeds, are now furnished and were opened on the 29th ult. In the new building there are two main floors. The ground floor, on the same level as the chapel, and having direct communication with it by means of a well-lighted corridor 6 feet wide, includes a large lecture-hall with sitting accommodation for 240 infants, five classrooms and a caretaker's living-room, whilst there are also separate entrances for boys, girls and infants. The upper floor is approached by two well-lighted stone staircases. On this floor is the schoolroom (64 feet by 34 feet), which has an open timber roof 26 feet high, and is a most cheerful apartment. Ten classrooms have access to the schoolroom. One of them, 25 feet by 21 feet in extent, is separated from it by a patent folding partition. When the two rooms are thrown into one it will be possible to seat 660 persons. The upper floor has communication with the gallery of the chapel. In the basement is a kitchen, storerooms, heating apparatus and other conveniences.

A HANDSOME clock-tower has been erected at Ripon, and was inaugurated on the 28th ult. with considerable ceremony. The Victoria Clock Tower (the name by which it is to be known) is Ripon's memorial of the Jubilee, and rises at the junction of the Palace and North Roads. The structure is 10 feet square and rises to a height of 43 feet, culminating in a Crown Imperial in copper. The finishing of the tower is rather uncommon. On the angles are four octagonal buttresses, which rise above the parapet in pinnacles, with carved finials and crockets. From these spring four flying arches or buttresses, and from four smaller pinnacles, corbelled out over the dials, spring four others. These eight unite in a keystone or carved boss, which carries the stone terminal on which he Crown Imperial rests. Of this manner of finishing a tower there are few examples. The principal ones are those of St. Giles's Church, Edinburgh (eight ribs); King's College, Aberdeen (four ribs); the Tron steeple in Glasgow and one at Newcastle. Formerly there was one at Linlithgow and one at Haddington. There are four dials enclosed within circular moulding within squares, the spandrels carved. On the stage below that of the clock the statue of the Queen occupies a canopied niche on the side fronting the city. Her Majesty is represented in a sitting position, the statue, as well as the rest of the carving, having been executed by Mr. Milburn of York.

A NEW pupil teachers' college has been erected in Clarence Street, Liverpool, and was formally inaugurated on the 30th ult. The new building, which has been designed to supersede the old premises in Shaw Street, which have hitherto had to do duty, although they had become sadly inadequate, have been erected at a cost of upwards of 17,000*l.* It has a frontage to Clarence Street and Pleasant Street, with an entrance for female students from each of these streets. The male students' entrance is from Green Lane. The main elevations are executed in buff terra-cotta and pink brick of specially selected tints. The style of architecture adopted may be described as a free treatment of English Renaissance, dominated largely by the requirements of modern education. Adjoining the college in Clarence Street is the principal's residence, now in course of erection. The classroom accommodation provided is for 569 students on the ground and first floors. The lowest floor is a half-basement, containing a tea-room 58 feet by 24 feet, a recreation-hall, accommodation for cloaks, lavatories, &c., store-room, heating apparatus, &c. There are separate entrances and staircases for female and male students, giving free exits and entrances. One of the female students' entrances is from Pleasant Street and communicates both with the basement and ground-floor. Another entrance will be from Clarence Street incorporated with the principal's house, which contains cooking arrangements in the basement in connection with the tea-room. One staircase is provided for the female pupil teachers, connecting the whole of the four floors, and another staircase from Green Lane, a side street, is provided for the male pupil teachers, also connecting the four floors, and giving access to their lavatories and cloak-rooms. The classrooms accommodate from thirty-five to sixty students each, and two pairs of fifty can be thrown together by sliding glass partitions. The science department, which occupies the top or second-floor, contains a chemical laboratory, 60 feet by 23 feet, giving accommodation for forty-eight students, with storage and preparation-room, balance-room and science teacher's room in connection

therewith. There is also a lecture and examination-room, 51 feet by 25 feet, divisible by a roller screen. The art class-room is 37 feet by 23 feet. Two of the classrooms are fitted with tables for science demonstrations, and one of them is, in addition, provided with light-proof shutters to all the windows to admit of the room being darkened for optical experiments, &c. An office for the principal commands the entrance for the female students from Pleasant Street. Special attention has been paid to lighting, heating and ventilation. The artificial lighting is by electric incandescent lamps suspended in clusters of three. The rooms are heated by hot-water pipes, and the corridors by means of radiators on the low-pressure system. Open fireplaces are also provided. A natural system of ventilation has been adopted, fresh air being admitted at the meeting rails of the windows, with other forms of inlet where required. Extraction is obtained by means of large air flues and roof extractors. The buildings have been designed and erected under the supervision of Messrs. T. Mellard Reade & Son, architects, 2 South John Street, Liverpool.

A HYGIENIC ATMOSPHERE.

AN ingenious invention which deserves the attention of, and adoption by all architects, builders, proprietors of places of entertainment and employers of labour has just been perfected and is being offered to the public.

We refer to the "Evertrusty Humidifier," of which Messrs. Wallach Bros. are the sponsors, and the purpose of which is to greatly improve the atmosphere in theatres, halls, factories, workshops, hospitals, &c., by moistening it (to an extent which can be regulated to a nicety), and thus rendering it agreeable and hygienic to breathe. This little appliance effectually obviates the unpleasant dryness which is so objectionable where the atmosphere is artificially warmed, or where numbers of persons are assembled either for recreation or work.

It is well known that the presence of a certain proportion of moisture (aqueous vapour) is necessary not only in order to render the air agreeable for breathing purposes, but especially for industrial purposes, and, as a general rule, it is to be noted that the warmer the air the higher should be the percentage of moisture. From this it naturally follows that in the case of enclosed spaces, in which a number of persons are continually breathing, the percentage of moisture requires to be increased by artificial means, as otherwise the heated air gradually becomes drier, and consequently heavier and more unpleasant to breathe. To keep the atmosphere in confined spaces sufficiently humid, according to the varying conditions of temperature and requirements, is the principal object of the

"Humidifier," and it is, as shown in illustration, an exceedingly simple contrivance, which can be easily fixed. As it has no delicate parts, it cannot get out of order, and it is remarkably inexpensive.

DEPTFORD FUND HOUSE.

THE Prince of Wales, who was accompanied by the Princess, visited Deptford on the 2nd inst. for the purpose of laying the foundation-stone of the Deptford Fund House. The fund, which is doing excellent work, has undertaken a vast field of labour, including the establishment of a sick kitchen for the issue of dinners to the convalescent poor; rescue and preventive work, a requirement of the greatest urgency and importance; a social club for the girls employed in the cattle market and elsewhere; the issue, on a large scale, of hospital and convalescent letters, &c.; the distribution of clothing and blankets, and of careful assistance of all sorts; recreative work, educational classes, and a variety of carefully organised branches, aiming to hold out the helping hand with care and discrimination; not pauperising or interfering with existing work, but helping and encouraging those uphill efforts which

22 & 23 SOHO SQUARE, LONDON, W.

are being made by the hard-worked clergy and helpers in the district.

The general idea of the new buildings which are to be the future home of the Fund is that of two large blocks; one facing the old road, consisting of a building of two storeys above the ground floor, containing accommodation devoted entirely to the charitable and philanthropic portion of the work, including club-rooms for girls and bath-rooms; and a higher building, with loftier rooms, for educational work and class-rooms, with club-rooms for men and boys and dormitories for girls, facing the new road.

These two blocks, which form two sides of a triangle, will eventually be joined by the large hall, &c, which forms the second part of the scheme and the base of the triangle. The centre of the triangle will be occupied by the staircase, lavatories, &c., and an area for light and ventilation. The staircase is ingeniously planned; it is, in fact, a double one, and is so managed that there is a staircase for men only, leading to the men's rooms, lavatories, &c., and another one for women only, leading to their parts of the buildings, an arrangement which has been carried out with success in many of the London School Board buildings.

In the basement there is on the old road side the sick kitchen, 28 feet by 16 feet, with larder, store-room, scullery, &c., and on the new road side a club-room for men, measuring 33 feet by 22 feet, boiler-rooms, coal stores and offices.

On the ground floor is the entrance hall from the new road, a porter's lodge, cloak-room, &c.; on the Creek Road side is the sick kitchen entrance, waiting-room and serving-room, with a lift communicating with the kitchen.

The first floor on the Creek Road side is entirely occupied by a club-room for girls, 40 feet by 22 feet, while on the new road side is the cooking classroom, 21 feet by 25 feet, exclusive of the scullery, store-room and larder. On this floor are also the secretary's and teachers' rooms.

The second floor is taken up on the Creek Road side by bathrooms for men and for women, while on the new road side the sewing classroom comes over the cooking classroom; and there is also a men's recreation-room.

The third floor brings us to the roof of the Creek Road block, which is an asphalte flat and capable of being fenced in and used as a recreation ground. On the other side we find a large laundry classroom over the sewing classroom, and a reading-room for men over their recreation-room.

The fourth floor of the block of buildings on the side of the new road consists of a range of capital dormitories for girls, with ample lavatory accommodation; and over the staircase are the rooms reserved for the caretaker.

Thus every care has been taken by the architect, Mr. Chas. H. M. Mileham, to secure the maximum of internal accommodation, while the elevations are quite simple and without any architectural pretension.

A SANITARY PAVEMENT.

THE pavement manufactured by the Cork Pavement Company, and the advantages of which were demonstrated to a somewhat numerous company on Monday last, although long past the experimental stage, is not so well known as from its merits it deserves to be. It has been laid for several years in certain positions the nature of which obviously renders the test of its qualities a severe one, and its behaviour has been such as to prove that it is durable, practically noiseless, non-slippery, non-absorbent and therefore sanitary. The ingredients of which the blocks (similar in size and form to those with which we are familiar in the hardwood now in such general use) are composed are granulated cork, bitumen, &c., subjected to a pressure of 600 lbs. to the inch, from which it emerges a homogeneous and hard, but at the same time elastic mass. It is claimed for this pavement that it affords an ideal foothold for horses and that its general adoption would greatly reduce the number, if indeed it did not entirely obviate the occurrence, of accidents through horses slipping, which are in certain circumstances—as after a shower, for instance—inevitable with any of the pavings at present in use. Whether dry, wet, or only damp it affords the same grip, and never requires the sprinkling of sand on it to supply its own deficiencies in this respect. As regards price it comes out about the same as some of the other pavements in use, but its greater durability renders it cheaper in the end. As we have mentioned above, the paving has been already subjected to practical tests, a notable one being the incline into the Great Eastern station at Liverpool Street. The gradient is one in sixteen, and the traffic is of the heaviest. The result of its behaviour during the six years it has been down is that the Great Eastern Railway Company have expressed their satisfaction in the most desirable manner by having other portions of their

In Operation at Eastbourne, Southampton, Warrington, Fenton, Henley-on-Thames, Houses of Parliament, Heston and Isleworth, Hampton Wick, Rangoon (Burma), Campos (Brazil), Slaughter Houses, Moscow, and numerous other places.
Manufacturers:—HUGHES & LANCASTER, 16 Great George Street, Westminster, London, S.W.

property paved with it as opportunities have arisen. It was also laid down in Princes Street station, Edinburgh, in 1892, and in 1898 the Caledonian Railway Company gave the following testimonial:—"We have pleasure in stating that we have lately examined your cork pavement laid in the cab-stands and cab entrance at Princes Street station about five years ago, and find that, although there is a heavy traffic, the pavement is still in excellent condition. The quantity laid by us was 1,800 yards. We would also recommend it for its noiseless and non-slippery character. We shall be very pleased, and will have every confidence, in recommending it to anyone making inquiries." The Chelsea Vestry have used it with satisfactory results. Strutton Ground was paved with it by the Westminster Vestry, who now contemplate putting it down in Orchard Street; and the London County Council, the Bermondsey and Paddington Vestries, Messrs. Tattersall and the North British Railway Company have also used and expressed satisfaction with it. Among private users who have had it laid in courtyards, stables, kennels, &c., may be mentioned the Duke of Westminster, the Duke of Bedford, Viscount Curzon, the Earl of Gosford, Mr. Panmure Gordon, &c.

ELECTRIC LIGHTING AT BALMORAL CASTLE.

THE arrangements for lighting Balmoral Castle by electricity are now being carried into effect, and during Her Majesty's recent stay there considerable progress was made with the estate work in connection therewith. Half a mile of iron pipes of large diameter has been laid for bringing the water from the upper portion of the Gelderburn to the site of the turbine house which is situated near the old sawmill, about a mile and a quarter from the castle. In some places ways 12 feet deep had to be blasted through the rock for laying the pipes. Provision is being made for two Gilkes vortex turbines, which, with a fall of nearly 80 feet, will give 80 horse-power combined. This power will be utilised in driving the dynamos for charging a large battery of accumulators at the castle, and also for lighting the lamps direct. The current will be transmitted by large cables laid underground all the way. The electric light will at first be limited to the Queen's private apartments, the ball-room and a few of the principal rooms in the castle, and the installation is expected to be in working order by the time Her Majesty returns to the North next month. Eventually more than 600 lights will be installed in the castle alone, but if electric lighting is extended to the stables and outbuildings about 1,000 lights will be required. The whole of the work, with the exception of fixing the turbines, is being carried out by the Commissioners' staff at Balmoral, assisted by some of the household electricians.

TESTS OF TIMBER.

THE recent issue of Circular No. 18 by the Division of Forestry of the United States Department of Agriculture again brings to attention the valuable work being done by that Division in the field of timber physics. The expression "timber physics," says the *Engineering Record*, is used because that is precisely the term which should be employed, and because, further, the tests of timber by the Division of Forestry do not represent results which would be found by the testing of timber ordinarily used, even in the best of structural engineering. It is probable that few people have been more interested in the timber testing of the Division of Forestry than civil engineers, and it is certain that no others have so earnestly advocated the support and continuance of the work. At the same time, it is unfortunately the case that civil engineers cannot accept the results of the Forestry tests as directly applicable to their regular practice in connection with timber structures.

This matter has come to be a most serious one, and it is full time that the real significance of the timber tests which have been conducted under Mr. Fernow's general direction should be accurately understood. In spite of his positive statements as to what engineers may take for their practical operations, as determined by his tests, his conclusions, so far as they affect engineering practice, are quite erroneous. These observations are made with a full and clear understanding as to their importance, and for the reason that certain conclusions expressed without qualification in Circular No. 18, as well as in some previous circulars, are not only untenable, but may be dangerous.

On the first page of Circular No. 18 Mr. Fernow states that "one of the questions which has disturbed the minds of men engaged in practical construction work has been whether and how far data obtained on small laboratory pieces are applicable to construction members of the size used in practice."

Every reputable engineer knows that such questions do not at the present time disturb the mind of any professional man;

PATENT

VULCANITE ROOFING.

Since the introduction of the patent Vulcanite Roofing into this country it has been adopted by a great number of leading architects for Public and Private Buildings, Hotels, Schools, Hospitals, Theatres, Mills, Warehouses, Breweries, Shops, Villas, Dwelling-houses, &c.

The temperature of the rooms immediately beneath the roof is more even in winter and summer than under any other roof. When properly laid repairs are never required, and all roofs are guaranteed. The roof-surface can be used as a garden, or for any other purpose. The cost of construction is less than even for a slate or tiled roof.

SHEET ASPHALTE for DAMP-COURSE, WATERPROOFING VAULTS, BRIDGES, TUNNELS, &c., is manufactured ready for use in lengths of 40 feet, and any width up to 40 inches, being more convenient than the usual damp-course slabs, and saving laps. Price lower and quality much superior to any similar article in the market.

SHEET ASPHALTE for ROOFING SHEDS, LIGHT BUILDINGS, &c., and for SARKING under slates or tiles, manufactured in five different qualities and in rolls of 15 superficial yards. It is easily laid, very inexpensive, much superior to felt roofing, and requires no annual coating.

Full particulars, Catalogues, Detail Sketches, Estimates, re Vulcanite Roofing; Samples, Prices, &c. re Sheet Asphalte, free.

THE PATENT VULCANITE ROOFING & ASPHALTE CO., LTD.,

28 VICTORIA STREET, WESTMINSTER, LONDON, S.W.

Inquiries from the North of England, Scotland, and Ireland, please address to Laganvale, Belfast.

Agents wanted in all districts where not yet represented for laying of Vulcanite Roofs and Sale of Sheet Asphalte.

he knows perfectly well that the ultimate resistance of full-size members can only safely be determined by testing those full-size members, and not by testing a small specimen, whether the material be timber, steel or anything else. That question might have been an open one twenty-five years ago, but it has long since been answered, and that answer is sufficiently attested by the expense to which engineers have put themselves and their clients in testing such full-size members as eyebars, columns and girders, to say nothing of actual structures. Apparently Mr. Fernow, and possibly those who are working with him, are unaware of these concepts of the best engineering practice of the present day.

The testing of the timber specimens and such full-size pieces as have been employed by the Division of Forestry has been conducted mostly by Professor J. B. Johnson, and latterly to some extent by Mr. S. T. Neely, and they cannot be given too much praise for the carefulness and thoroughness with which they have conducted their operations. They have contributed to the subject of timber physics an amount of experimental knowledge which is of untold value, and it is the last thing the *Engineering Record* wishes to do to detract in the slightest degree from the merit of their work; but it is necessary to point out precisely what they have done as well as what they have not done.

Both the test specimens and the full-size pieces which they have tested have not in a single instance been selected either from a lumber yard or from the timber which has been cut for market purposes; whereas it is from those sources, and those only, that the engineer must select his material. The sticks for the Forestry tests have been selected by able Forestry experts, and their very efforts to find such as they consider fairly representative of the timber which they are to test prevent them from securing such material as the engineer is constantly liable to use. In other words, their regular sticks correspond to the very best pieces which the engineer ever secures, and thus do not represent the average run of his timber. The lumber companies cut everything which they think they can market, and they manage to market practically everything they cut. The Forestry experts have usually selected the butt sticks of the very best trees that the lumberman ever secures, and their test specimens are usually clear heart material. All the small specimens, numbering thousands, which the Forestry Division has tested are, besides, fairly if not entirely free from knots. With such special grades of material it is not a matter of surprise that Mr. Fernow should find the unit resistance of small sticks so nearly equal to that of the large ones as to induce him to ignore the difference.

On page 10 of Circular No. 18 he concludes :—"Average values derived from a large series of tests on small but representative material may be used in practice with perfect safety, and these averages are not likely to be modified by tests on large material."

That conclusion is contradicted by the experience of every engineer who has had practice with full-size pieces, such as are used in structural engineering. Furthermore, the same conclusion is contradicted by the full-size column tests made at the Watertown Arsenal and by Professor Lanza. The Forestry tests are probably correct for the special quality of timber which they have employed, but the error arises from the fact that they have not used the quality of timber which an engineer must introduce into his structures. The tests at the Watertown Arsenal in a number of instances have showed that the unit resistances of small pieces of considerable size were only about half of those found by testing full-size members from which the small pieces were cut, and those instances can scarcely be considered extreme. This matter is one which needs to be set forth in its true relation to such timber members as are regularly used in the civil engineer's practice. In such cases it is absolutely essential, as it is in metal members, to test not only full-size pieces, but full-size pieces of the same quality and character as those actually put into structures.

SPITALFIELDS MARKET.

AT an early meeting of the London County Council a proposal will be made by the public control committee that powers should be sought in the next Session of Parliament for the acquisition by the Council, either by agreement or compulsory, of the freehold and other interests in Spitalfields Market. In a report upon the matter the committee state that the freeholders and owners of the market are the Goldsmid Trustees, who, in 1882, leased it to a Mr. Horner for eighty-four years at a rental of 5,000*l.* per annum. The area of the market was now about 2¾ acres, and the interior, to the extent of about 1½ acre, was covered by a large glass and iron roof. Under Mr. Horner's management the revenues from the market had increased year by year; in 1887 they were 11,338*l.*, and in 1897 19,353*l.* Mr. Horner had spent about 80,000*l.* in recon-

Messrs. W. B. SIMPSON & SONS, 99 St. Martin's Lane, W.C.

structing the market; but notwithstanding this the market area was altogether inadequate for the business carried on. Consequent upon this there had been an overflow into the surrounding streets to such an extent that it had created a serious public nuisance by interfering with the traffic, especially in Commercial Street. Various improvements in the traffic arrangements had, at the suggestion of the committee, been gradually carried out, but they now believed that little further in that direction could be done until the market was acquired by the Council and its area enlarged. The committee are of opinion that the acquisition of the market will not involve any cost to the ratepayers, as the income would probably not only be sufficient to defray the cost of acquisition, but would ultimately prove a profitable investment.

THE VESTRIES AND ELECTRIC LIGHTING.

THE Chairman of the House-to-House Electric-Light Supply writes:—

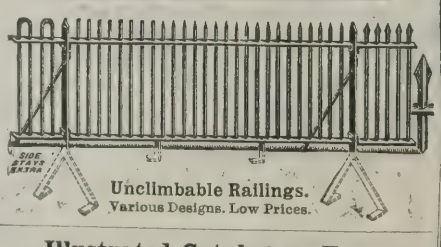
From the statement of policy recently announced by Mr. Ritchie in the House of Commons, it appears that the Board of Trade considers that section 1 of the Electric-Lighting Act of 1888 imposes on the Department the duty of granting competing provisional orders (preferably to local authorities) unless strong reason can be shown to the contrary; and, further, that the efficient exercise of its powers by an existing company is no reason why it should enjoy undisturbed occupation of its area.

For the justification of this opinion the Board of Trade relies partly upon the language of the Act and partly upon the report of Major Marindin in 1889.

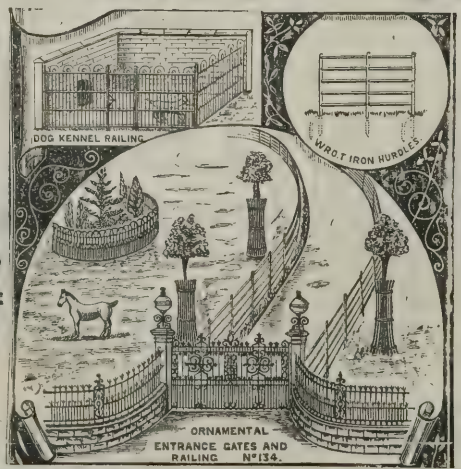
With regard to the language of the Act the wording of the section is as follows:—

"The grant of authority to any undertakers to supply electricity within any area, whether granted by license or by means of a provisional order, shall not in any way hinder or restrict the granting of a license or provisional order to the local authority or to any other company or person within the same area."

These words were introduced as an amendment to the Bill by Sir George Campbell (Hansard, vol. 326, third series, p. 873), and the argument employed in recommending them was, that inasmuch as it was the admitted intention of Parliament that the Electric-Lighting Acts should not confer a monopoly, such words were either surplusage, and therefore unobjectionable, or were wanting, and therefore necessary.



Sir George Campbell was followed by Sir Michael Hicks-Beach, at that time President of the Board of Trade, who deprecated the amendment on the ground that the Bill had been rendered necessary in order to give greater encouragement to capital than was afforded by previous legislation, and that the words might be very mischievous by defeating the object in view. Sir Michael Hicks-Beach was followed by the late Mr. Mundella, the President of the Board of Trade, who endorsed this opinion and said that the words in question might be held to promote "indiscriminate competition" to which the best opinion was opposed, adding also that Mr. Chamberlain and Lord Herschell supported this view. The debate was then adjourned, and on June 11 the amendment was agreed to without further discussion.



Now surely, these proceedings, though somewhat inconsequential, meant that Parliament intended to convey, on the one hand, an announcement to the consumer that he should be protected against the inefficient exercise of powers by the investor; and, on the other hand, an announcement to the investor that he should be protected against injurious competition so long as he discharged his responsibilities to the consumer.

How, then, can it be contended that section 1 of the Act of 1888 imposes on the Board of Trade the duty of granting a competing order unless strong reason can be shown why it should be refused? Is it not clear, on the contrary, that, whilst Parliament intended to deny that a provisional order conferred an absolute monopoly (as might perhaps have been contended in the absence of the clause), the last thing Parliament intended to deny was that a provisional order conferred a conditional monopoly so long as the powers vested were efficiently exercised, and therefore that the language of the Act imposes on the Board of Trade the duty of refusing a competing order unless strong reason can be shown why it should be granted?

Investors, of course, knew perfectly well that if they failed in the efficient exercise of their powers they would have to make room for others better qualified than themselves, and in this sense, but in no other, it may be said that a company applying for a provisional order came with its eyes open to the possibility of competition. But investors assuredly believed that, provided they discharged their statutory obligations, the traditional practice of Parliament would secure them from disturbance, and if they had thought that after risking their

money they would have been deprived of the fruit of their enterprise in the event of success, the Act of 1888 would certainly have proved as ineffectual as the Act of 1882 in inducing the requisite investment of capital, as Sir Michael Hicks-Beach and the late Mr. Mundella said at the time.

With regard to the report of Major Marindin, the Board of Trade relies upon the fact that in 1889 they were advised that a second order might be granted under certain conditions in the same area.

Now, it is no disparagement of Major Marindin's report to say that its recommendations are not good for all time, and, assuredly, the conditions in regard to electric lighting which prevailed in 1889 bear no resemblance whatever to those which prevail to-day. In 1889 the metropolitan areas were not occupied, and the methods of producing and distributing electricity were still in the experimental stage; no one could tell whether the important areas into which London is divided ever would be occupied by the then occupants, or, if they ever were, whether the continuous system or the alternating system or either or both of them could be depended upon for a sufficient supply. What more reasonable, in such circumstances, than that concurrent powers by different methods of supply should be granted in the same area? But it is not because a policy based upon such recommendation in the past has worked with advantage to the consumer and without prejudice to the investor that it can be pursued with equal advantage to-day, when most of the areas are fully occupied and when experience has proved that both systems in use may be depended upon for both cheapness and quality. What magic can there be in the grant of two orders in every area? Two orders may be too few in one area and too many in another, or they may be too few in one area at one time and too many in the same area at another time. The desirability of two orders, in short, is wholly a question of circumstances, and of circumstances which have almost if not entirely passed away. The present companies, who have struggled bravely with the initial difficulties of the industry, and who have so far returned most inadequate dividends to their shareholders, do not set up any claim to monopoly, but they protest against the indiscriminate competition which the Board of Trade is disposed to promote in the supposed interest of the consumer, but really at the instance of certain companies who, in view of the profits now apparent, are seeking to invade the areas of others, and of certain local authorities who are impelled in the circumstances to try to forestall them.

THE DEANSGATE GOODS DEPOT.

ON the 1st inst. a part of the great depôt of the Great Northern Railway Company in Deansgate, Manchester, was opened for traffic. Hitherto the goods traffic of the company for the Manchester district was entrusted to the Manchester, Sheffield and Lincolnshire Railway Company, but owing to differences between the two on account of the extension to London, the Great Northern Company decided to become entirely independent, and an Act was obtained authorising the erection of a goods depôt in Manchester on a site which is bounded by Deansgate, Great Bridgewater Street, Peter Street and Watson Street. The works are said to have already cost about a million, and were carried out from plans prepared by Mr. W. T. Foxlee. In laying out the site, it was arranged to use the frontage to Deansgate for several shops, and offices for the staff are in course of construction in Peter Street. The depôt is on two levels. The connection of the new works with the Cheshire Lines is, says the *Manchester Guardian*, made by a double junction, which has been laid in at the east end of the Cornbrook viaduct, about half a mile from the Central Station. Three lines of way are carried upon a viaduct as far as Bridgewater Street, where they diverge into twelve other sets of rails, ten of which are continued over the streets into the warehouse, situated at the northern end of the large area of land which has been acquired by the company. The remaining two lines are carried down by inclines, one on each side of the site, to the street level, where access is obtained to a commodious goods yard, a large area of which is covered by the viaduct carrying the rails into the warehouse. These inclines are constructed for the most part of steel girders resting upon brick piers and terminating with brick arches and retaining walls. The approach viaduct, of rather more than a quarter of a mile in length, consists of brick arches with steel girder bridges at the street crossings; where it is carried over the lower yard it is constructed entirely of steel, supported by built-up stanchions of the same material, the flooring consisting of jack arches, covered with concrete and rendered waterproof by means of asphalte. The warehouse, which is of fireproof construction throughout, is 267 feet long and 217 feet wide, and when complete will rise to a height of about 75 feet above street level. The lower floor, which is at street level, contains lines of rails running alongside platforms, with ample roadways for carts and lurries; the upper floor, the approach to which from the railway has been described, is also

occupied by rails and platforms, with ample carting space, connected by an inclined road with Watson Street. The lower yard, situated at street level, will have four entrances, conveniently situated at the corner of Deansgate and Peter Street, Great Bridgewater Street and Watson Street. Ample siding accommodation will be provided for dealing with every class of traffic, the roadways being paved throughout either with granite setts or Australian hardwood blocks. Cranes, capstans, &c., are provided for dealing with the traffic in the most expeditious manner. It will thus be seen that there are practically two goods stations, one over the other. Above the upper set of rails in the warehouse there are three floors for the storage of merchandise, grain, &c., extending over the full area of the building.

The building is erected in a most substantial manner, the lower portion consisting of blue brickwork in cement, and the upper portion of hard local bricks relieved by blue-brick bands. The floors, which consist of steel girders with jack arches between, are covered with concrete and supported by built-up steel stanchions, these resting upon massive granite blocks supported upon blue brickwork in cement. The whole of the foundations are carried down to the solid red sandstone. Ample communication has been provided between the various floors by means of hydraulic hoists, jiggers, &c., working through numerous hatchways; hydraulic cranes are also fitted on all the platforms for the purpose of conveying goods from the waggons to the carts and *vice versâ*. The power for this work is obtained from the Corporation mains. The building throughout, as well as the adjacent yards, are lighted by electricity, also supplied by the Corporation.

Under the central portion of the site there exists in tunnel, between 35 feet and 40 feet below the surface, a disused branch of the Bridgewater Canal, and it has been arranged in connection with this waterway to construct a commodious basin dealing with canal traffic, which will be connected to the warehouse by means of hydraulic lifts. This new goods warehouse will then be the only railway warehouse in Manchester having direct communication with the Ship Canal. The company have also under consideration the desirability of constructing a vegetable warehouse providing special facilities for dealing with a large trade in potatoes, roots and vegetables. A handsome block of offices to accommodate the staff of the goods department is in course of construction at the part of the site that abuts upon Peter Street, and under an arrangement with the Corporation the company are constructing a range of shops extending for a distance of 600 feet or 700 feet in Deansgate, between Peter Street and Great Bridgewater Street. Something will also be done at this point in the way of widening Deansgate, which thoroughfare may in the end be improved rather than have its appearance injured by the construction of the depôt.

The main contract for the works which have thus been described is being carried out by Messrs. Robert Neill & Sons, of Manchester, the steelwork being supplied by Messrs. Heenan & Froude, of Newton Heath, Sir William Arrol & Co., of Glasgow, and Messrs. Keay, of Birmingham. The hydraulic machinery has been chiefly supplied by Sir William Armstrong, Whitworth & Co., and a portion has also been supplied by Messrs. Musker and Messrs. Higginbottom & Mannock.

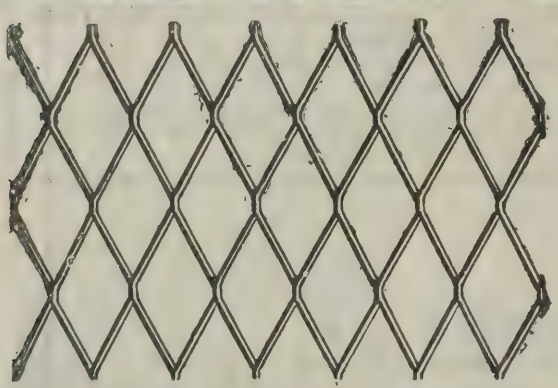
PATENTS.

[*This List of Patents is compiled specially for this Journal by Mr. G. H. Rayner, of the firm of Rayner & Co., Consulting Patent Agents, 37 Chancery Lane, London, W.C., from whom all particulars and information relating to Patents may be had gratuitously.*]

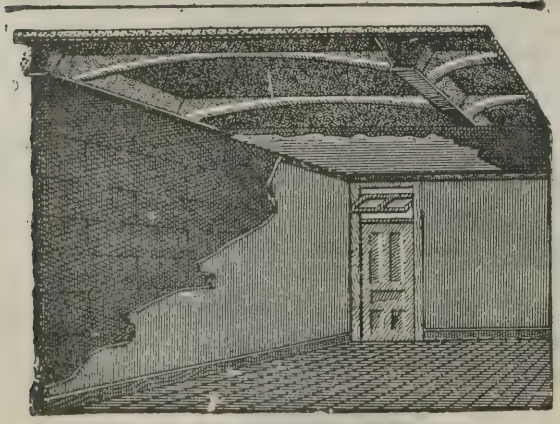
APPLICATIONS FOR PATENTS.

13649. Edwin James Masters and George Henley Couves, for "An appliance to stand on to clean or paint windows externally."

13746. William Beak, jun., for "Improvements in and relating to brick-kilns."



13928. Ralph Collenette, for "Improvements in brick presses."



14011. William Appleton, for "Improvements in dies for brick-making machines."

14993. Martin, for "Brick-making machine."

TO INVENTORS.—Patents for Inventions, Trade-marks and Designs secured; every assistance given to inventors. Specialists in Building matters. Information free.—Messrs. RAYNER & CO., Patent Agents, 37 Chancery Lane, London, W.C.

THE NEW EXPANDED METAL

Meshes from $\frac{1}{8}$th in. to 6 in. wide. Strands from 24 B.W.G. to $\frac{3}{16}$th in. thickness of steel.

FOR BUILDING CONSTRUCTION, as supplied to a large number of important Buildings, both Public and Private, in this country and abroad.

FOR SOLID PLASTER PARTITIONS, 2 inches thick, with Expanded Metal Lathing. Fireproof, vermin-proof and practically sound-proof.

FOR FIREPROOF LATHING, for attaching to wooden joists and studs, for walls and ceilings, also for suspended ceilings, ornamental mouldings, encasing columns, girders, &c.—no cracking or falling away of plaster to be feared.

FOR CONCRETE FLOORS WITH EXPANDED METAL.—The remarkable results and advantages of these will be better understood by perusal of the Report hereinafter referred to.

FOR EXTERIOR WALLS OF BUILDINGS.—Cement applied to Expanded Metal is not liable to crack or fall away through changes of temperature.

FOR FENCING, TREE GUARDS, WINDOW GUARDS, as supplied to the Royal Parks, leading Railway Companies and landed Estates throughout the Kingdom.

ORNAMENTAL. STRONG. CHEAP.

OTHER USES FOR EXPANDED METAL.—These are innumerable. It can be used wherever lattice-work is required, from a letter-rack to a lift-shaft, for garden bordering and archways. Is highly ornamental and exceedingly durable, having no joints to rust away.

Being expanded by rapid machinery it is considerably cheaper, strength for strength, than any other description of metal lattice-work.

BRASS, ALUMINIUM, or any other ductile metal can be expanded, and the effect is very pleasing, and here again the absence of joints gives great durability to the metal, and the rapidity of manufacture allows of very low prices.

CATALOGUES AND PRICE LISTS can be obtained on application. Also copy of a REPORT by an EMINENT FIRM of ENGINEERS on the use of EXPANDED METAL IN CONCRETE.

THE WEEK.

MR. JUSTICE HAWKINS is an admirable judge, and he never allows his attention to the details of a case to be diverted. But we hope he will not turn his keen wit upon witnesses who have to prepare plans for his court. On Tuesday at the Sussex Assizes his lordship had to try a labourer who was charged with feloniously and maliciously setting fire to a stack of hay at Arundel. A local surveyor produced plans showing the position of the stack, and deposed to distances between various points. Mr. Justice HAWKINS, on looking at the plans, complained that a rough road on the river bank was shown much the same as the hard macadamised roads of the neighbourhood. The witness said, "We couldn't show every stone, my lord." His lordship retorted, "I didn't suppose for a moment you had sufficient observation or sufficient scientific knowledge to do that." He also complained that a telegraph pole looked like "an ornamental ant." It is needless to say the judge's remarks, which were an imitation of Dr. JOHNSON's manner, were received with the usual "laughter" which is always awaiting displays of the kind. But surely Mr. Justice HAWKINS cannot expect that a plan should resemble a view by a landscapist. What distinguishes a rough road from a high road on a plan is the irregularity in the course and the absence of uniformity in the width. With a telegraph-pole it is sometimes convenient to indicate the direction of the wires regardless of the resemblance to an ant. The surveyor appears to have done his work properly, and did not, as well as we can judge, deserve a judicial rebuke.

THE Edinburgh Town Council on the 6th inst. considered the various suggestions about sites for the proposed Usher Hall. The following motion was adopted by a majority of three votes:—"That the magistrates and Council resolve to make an offer of 65,000*l.* to the North British Railway Company for the area at Port Hopetoun, for a site for the City Hall, and if this is not accepted, that no other steps be taken towards acquiring the area for this purpose, and delay consideration of the motion and amendments until an answer is received." It will be impossible for the Town Council to grant the money, if the railway company are willing to accept the amount, without the sanction of Parliament. After so many discussions of rival schemes it is not impossible that Mr. USHER will be asked to withdraw his offer.

THE following students have passed the June examinations of the Royal Institute of British Architects:—*Preliminary.*—L. P. Abercrombie, C. J. H. Ascroft, S. B. Ashworth, H. W. Asman, A. H. THE congress of the French Archæological Society which was opened at Bourges on the 5th inst. was a great success. M. DE MARSY presided, and in his address he spoke with much sympathy of Spain and its trials. M. DE VILLEFOSSE delivered an eulogium on the late A. DU CAUMONT, the founder of the Society, and who rendered many other services to archæology. There were excursions to Dun, Meillant, La Celle and Bruère. The Château d'Amboise was also visited. Much attention was given to the house of JACQUES CŒUR and the cathedral. The stained-glass windows were described by the Marquis DE MELOIZES. The musée of Bourges is rich in ivories and enamels, which were duly appreciated. There were about 250 subscribers who attended the conference.

ON Friday last the Académie des Beaux-Arts presented to the late secretary, the Comte HENRI DELABORDE, the medallion which was specially sculptured by M. CHAPLAIN. It is in gold, and is of rectangular shape. On one side is a portrait of the recipient, who is in his eighty-seventh year; on the other side is an inscription which testifies that the Académie accepted M. DELABORDE's resignation with the greatest regret, and were grateful to him for his long and eminent services. The resolution is surmounted with attributes of the fine arts.

THE restoration of the tower and spire of Salisbury Cathedral having been completed, at a cost of about 14,000*l.*, under the direction of Sir A. W. BLOMFIELD, a thanksgiving service was held on Monday last. The Archbishop of CANTERBURY preached, and spoke of the privilege of being able to symbolise the glory of Christian worship, although fervent prayer might be offered in a building that resembled a barn. The spire is of a later date than the body of the cathedral, and it showed great daring on the part of the architect, or more skill in estimating the strength of masonry walls than is commonly understood, to raise such a mass on another architect's work. The older masonry had to be strengthened in various ways. According to PRICE, one hundred and twelve additional supports, exclusive of iron bands, were introduced. Windows were filled up, and three hundred and eighty-seven superficial feet of new foundation were constructed. It is amazing that so compound a structure should have endured for so long a time, and we hope that after Sir A. W. BLOMFIELD'S restoration it will endure for as many more centuries. The height of the spire has been calculated at different figures, but apparently four hundred and four feet is correct.

FOR the purposes of the Building Act the district of Fulham (hitherto comprising the whole of the parish of Fulham) has been divided by the County Council into two districts, viz. North Fulham, comprising that part of the parish lying to the north of the Fulham Road and High Street, Fulham, down to Putney Bridge; and South Fulham, comprising that part of the parish lying south of the above roads. At a meeting of the County Council on the 5th inst., it was decided to appoint Mr. STANLEY F. MONIER-WILLIAMS district surveyor for South Fulham, and Mr. FREDERICK W. HAMILTON, A.R.I.B.A., district surveyor for North Fulham.

EDMUND BURKE.

A CENTURY has elapsed since the remains of EDMUND BURKE were laid in a grave in the church of St. Mary and All Saints, Beaconsfield, and until Saturday last there was no memorial of a man who served his country well erected in England. There is a statue of him outside the college where he studied in Dublin, but the work of BURKE was not done in Ireland. Now there is a panel in the church which records the undying affection in which the name of EDMUND BURKE, patriot, orator, statesman, who lived at Butler's Court, formerly Gregories, in the period from 1769 to 1797, is held in local memories.

BURKE'S life is part of the history of England, and the purity of his character was equal to his ability as an orator or a writer. The statesman whose vision reached not only over the globe, but likewise extended to the remote future, had the affection of a farmer for the land he cultivated. Like many an old warrior, his wish was to find repose in a simple parish church, and happily it was granted.

The charm of BURKE has not ceased, although there was no sculptor's memorial to record his generous efforts to benefit the oppressed and aid unlucky men of letters. Many writers were glad of the opportunity offered by the unveiling of the memorial on Saturday to pay once more a tribute to the patriot who described himself truly as having no arts but manly arts, and who in his first session as a member considered it his duty "to analyse the whole commercial, financial, constitutional and foreign interests of Great Britain," in order to prepare himself to be useful to his constituents. It is not permitted to us to recall BURKE'S political services. But as, unlike the statesmen of his time, he was inspired by a genuine love of art, although he was never sufficiently rich to become a collector, it may be allowed us to glance at one side of his character which is generally overlooked.

His name alone indicates that BURKE was an Irishman. He was born in Dublin in 1730. He was of mixed race, and through his mother he inherited the blood of EDMUND SPENSER the poet. His father was a wealthy attorney, and BURKE is supposed to have always possessed a competence derived from him or from his elder brother. But after receiving education in the Dublin University, when he came to London to study for the Bar he was willing to write for publishers, and that inclination rarely belongs to men who are at ease in money matters. BURKE also was, it is said, a candidate for a professorship of logic in the University of Glasgow. It is believed, too, that he had thoughts of emigrating to America. His early life in London corresponded with that of many a literary adventurer. But he was not disposed, as far as is known, to waste his strength in proving his versatility. His first known pamphlet was a "Vindication of Natural Society," in the manner of Lord BOLINGBROKE, in which we have the germs of the conservatism which marked BURKE'S later years. It excited much attention. It was immediately followed by the "Philosophical Inquiry into the Origin of our Ideas of the Sublime and Beautiful," which also showed speculative skill.

Two years after the publication of the "Inquiry" BURKE was introduced to "Single Speech HAMILTON," who was a *protégé* of Lord HALIFAX. Anyone who will have the courage to read HAMILTON'S "Parliamentary Logick" will be struck with the pains taken by the author to become an invincible debater. A successful career in the House of Commons appeared to him to consist in intellectual fencing, and he realised he could not find any one who was better adapted to practise with than EDMUND BURKE. When HAMILTON was appointed Chief Secretary for Ireland, he brought BURKE with him to Dublin as his private secretary. BURKE'S genius was at once manifested, and it was not long until he broke with his patron, who was disappointed when he found he was not to have a "ghost" who was to gain for him the credit of statesmanship, and also without any cost. The couple of years which BURKE lived in Dublin enabled him to become acquainted with JAMES BARRY. The painter exhibited a picture, *St. Patrick Baptizing the King of Cashel.* A royal baptism would not now be thought a novel subject, but what gave interest to the Irish incident was that the saint had placed his sharp-pointed pastoral staff on the king's foot, and as the neophyte imagined the infliction of pain was part of the ceremony he bore the transfixing with submission. To BURKE, who may have often thought about the neglect of Celtic legends by poets and artists, the picture appeared as marking the commencement of a new era in painting. He sought out BARRY, brought him to London, and from his scanty and precarious income supplied him with enough money to visit Italy. BARRY was the most wayward of young geniuses. His Hibernian pugnacity drove him into rebellion with everybody of influence in Rome, and he plagued BURKE with relations of the hourly martyrdom he was undergoing in the cause of high art. There are no wiser or more considerate letters in the language than those which BURKE sent in reply. In age there was only a difference of ten years between the two, but in the correspondence BURKE appears to be a sympathetic elder who endeavours to mollify a peevish boy. One passage is well known, but will bear repetition:—"Believe me, my dear BARRY, that the arms with which the ill dispositions of the world are to be combated, and the qualities by which it is to be reconciled to us, and we reconciled to it, are moderation, gentleness, a little indulgence to others, and a great deal of distrust of ourselves, which are not qualities of a mean spirit, as some may probably think them, but virtues of a great and noble kind, and such as dignify our nature as much as they contribute to our repose and fortune, for nothing can be so unworthy of a well-composed soul as to pass away life in bickerings and litigations, in snarling and scuffling with every one about us."

BURKE could be satisfied that he had enabled a painter with great natural gifts to overcome many of the obstacles which were in the way of the builder's son, but in spite of the epistles which were those of a wise elder brother, BARRY never attained moderation and gentleness, nor ceased from bickering and scuffling. The painter's life continued to be a combat in London as in Rome. BURKE was, however, spared the pain of witnessing BARRY'S removal from the professorship of painting and expulsion from the Royal Academy. BARRY was not ungrateful to his friend; his proud nature prevented him from public acknowledgments of his indebtedness to BURKE, but it would have been easy to express obligations to his friend's intellect, although he might be silent about banker's drafts.

BURKE was one of those men from whose simplest talk something could be gained by a listener, and BARRY must have profited by many a discourse for his benefit. Dr. JOHNSON said that to stand under an archway during a shower of rain if BURKE were there would be an opportunity for improving the mind. He appeared also to be indifferent about the value of his thoughts. O'CONNELL used to maintain that BURKE must have been "Junius," for he alone would not care to claim the renown which was given to the anonymous letters. That conclusion was probably erroneous, but it was a shrewd appreciation of one of BURKE'S qualities. Those among his contemporaries who knew him best believed he was capable of accomplishing any feat he cared to undertake in literature, and success would be to him of no more value than a glass of good wine. Hence he was credited with the authorship of REYNOLDS'S Discourses. There is no doubt he helped the President of the Academy to attain the *art de bien penser.* NORTHCOTE does not hesitate to say that REYNOLDS was at one time grossly illiterate, and he deserves credit for profiting by the companionship of JOHNSON and BURKE. Of his two mentors he preferred the latter. According to FARINGTON, "Of all the distinguished men with whom Sir JOSHUA was acquainted, Mr. BURKE stood highest in his estimation of their mental powers. He thought Dr. JOHNSON possessed a wonderful strength of mind, but that Mr. BURKE had a more comprehensive capacity, a more exact judgment, and also that his knowledge was more extensive; with the most profound respect for the talents of both, he therefore decided that Mr. BURKE was the superior character."

It would be impolitic on the part of REYNOLDS if he failed to submit the scheme of the successive Discourses to the friend that was valued so highly, and whose reticence was one of his remarkable qualities. The Discourses were experimental, and the success of the Academy was supposed to depend in some measure on their favourable reception. Can we imagine that the counsel of so far-seeing a statesman as BURKE would be unsought? The

Discourses reveal a loftiness of thought, a method in arrangement, a subserviency of parts to an end which are not found in REYNOLDS's contributions to the *Idler* (a couple of essays that inflicted a vertigo on the author), or in his other acknowledged writings. The omission of any reference to BURKE except the footnote in the Eighth Discourse, "This was inadvertently said: I did not recollect the admirable treatise 'On the Sublime and Beautiful,'" is just the kind of remark that would be put in to turn aside attention from the true author. It also deserves to be noted that BURKE in his eulogium on REYNOLDS carefully avoids a reference to the late President's literary efforts or knowledge—the subject on which he might be considered the most competent judge. All he says is that REYNOLDS possessed the theory as perfectly as the practice of his art, and that his talents were not meanly cultivated by letters. Compare those guarded words with the generous fluency with which BURKE described REYNOLDS as a portraitist. "In taste, in grace, in facility, in happy invention, and in the richness and harmony of colouring, he was equal to the great masters of the renowned ages. In portrait he went beyond them; for he communicated to that description of art, in which English artists are the most engaged, a variety, a fancy and a dignity derived from the higher branches, which even those who professed them in a superior manner did not always preserve when they delineated individual nature. His portraits remind the spectator of the invention of history and the amenity of landscape. In painting portraits he appeared not to be raised upon that platform, but to descend to it from a higher spirit." Why was BURKE so eloquent in speaking of REYNOLDS's portraits and so silent about the Discourses? Was it not likely that he refrained from eulogising them because they were his own work, and he was too honest a man to descend to that depth, although he could without any thought of self-sacrifice leave any credit which they might gain to the friend whose experience was embodied in them? There is much in the Discourses which was beyond BURKE's knowledge, for he was no traveller, and he could not speak with confidence about the malpractices of contemporary artists abroad. But about the grand style, general ideas, nature and fashion, mixed passions, standards of taste, &c., there was no more competent authority in those days than EDMUND BURKE.

It is commonly supposed that BURKE could not write a book for artists or aid in its production because he was the author of the "Philosophical Inquiry into the Origin of our Ideas of the Sublime and Beautiful." It appeared in 1756, but BURKE is believed to have composed the greater part when he was a youth of nineteen. The essay was a daring effort. Art and poetry were supposed to be connected with pleasure. BURKE argued that terror was the source of the sublime, while from love (which does not invariably bring pleasure) the effect of the beautiful was derived. Of late years people have become sceptical about the creation of anything sublime in poetry or art. TURNER found it necessary to represent the python which APOLLO slays as extending many a rood, and as tearing up trees and unloosening hills in its death throes. In the drawing in the Water-Colour Society's exhibition the late BURNE-JONES also acknowledged his incompetence to excite terror, unless he was allowed to show the sea monster that was to attack the *petite* ANDROMEDA as an ocean telegraph roll or a piece of vulcanised tubing of countless folds. Visitors look on both works without fear, and naturally conclude that, with the utmost latitude about "greatness of dimensions," nothing terrible can be represented, and of course there can be no sublimity. TURNER's attempt is undoubtedly impressive, but the later artist's is ridiculous.

What has caused the neglect of BURKE's essay is, however, that psychologists of all schools in the eighteenth century arose against him for maintaining that differences of taste are only apparent, and that all men in effect perceive nearly in the same manner, and that therefore the principles of taste are entirely uniform, although men possess them in very different degrees. If that were true there would be no need to have discussions about a standard of taste, and as regards æsthetics, at least, the psychologist's occupation would be gone. BURKE was therefore treated as a man who took up a subject with which he was unacquainted, and it required some courage to notice his attempt to explain the sublime and beautiful.

But foreigners have hesitated about accepting so summary a conclusion. THÉODORE JOUFFROY, who has the most likelihood of becoming the representative of French æsthetics in the nineteenth century, has shown extraordinary respect for BURKE's system. He considers that BURKE's theory of a dilatation or contraction of the nerves, according as a sublime or beautiful object comes in contact with them, is not exact, and would reduce æsthetic emotions into physical sensations. He also declines to agree with BURKE's democratic belief in the universality of taste. But he says what BURKE established about sensible causes for æsthetic emotions is true; that the sublime is the result of one effect and the beautiful of another. As to BURKE's expression about our love for the beautiful, JOUFFROY says there is no better manner of expressing what we feel before a beautiful flower, bird, or tree, whereas for a sublime thing we cannot say "Je l'aime," although it is doubtful whether BURKE was altogether correct when he said there was something of fear and of sorrow in the feeling of sublimity. Throughout his reasoning JOUFFROY is as respectful towards BURKE as towards KANT, and it is with pride he acknowledges whenever the Irishman's and his own theories are in agreement.

Great artists are not to be made by theories of the sublime and beautiful, although they may prevent occasional errors. They begin with words, and commonly never pass beyond the verbal condition. BURKE was of too expansive a nature to be a great artist, but he was a master of language, and could use it as if he were a giant. Reading one of BURKE's speeches or pamphlets has an effect not unlike what is produced by considering a cast of one of MICHEL ANGELO's figures. In both there is a departure from the Attic spirit, but their power is irresistible. In one as in the other there are defects, but that weakness shows they are more akin to modern mortals than are the old Greeks. BURKE served art in other ways besides talking with REYNOLDS and BARRY and writing an inquiry about the sublime. He was the first of our statesmen to demonstrate that the expenditure of public money on art was the duty of a nation. There was no stricter economist than the Paymaster-General, but he held that wealth should be the obedient slave of virtue and public honour, and as such should be used to embellish a country with noble works. He believed that as architecture impresses, by the laws of nature and of reason it should become the statesman's care. If in those days a Minister of Fine Arts was considered a necessity, there could be discovered no more fitting man for the office than EDMUND BURKE.

THE GREEK STAGE.

THE eagerness not only of the official German archæologists, but of a large number of ordinary students, to examine if not to share in the explorations in Greece appears surprising to many people in this country. As yet classical archæology cannot be said to be popularised among us. For a long period the Universities were satisfied with sending out a travelling student, or, it may be, two, and the representatives were generally allowed to follow their own inclinations. As a rule, they went wherever the discomforts were least and information on what was to be seen was most abundant. With the Germans, on the contrary, a sort of archæological world is first worked out from books, which is more or less accurate; but the ambition of every student is to verify his own speculations. Hence it is that each year excursions are arranged for students to those parts of Greece where excavations are in progress, and there are usually far more applicants from the German universities than can be accommodated. Many of them are disappointed, but what they endure is not identical with the grief which comes to the respectable excursionists from this country. Our representatives are annoyed at allowing themselves to be "taken in;" the German student commonly is sorrowful because the pictures he painted of antiquity with the aid of imagination are found to be delusions. He returns a sadder but a wiser man, and henceforth is competent to make the deductions from the descriptions of classic authors which are always necessary

to those who are eager to arrive at the truth. His companions are like himself, and hence there is now arising in Germany a class of scholars who are less disposed than their predecessors to accept old-fashioned information, no matter what reverend authorities may certify it, unless it can withstand all the scepticism which comes from a scrutiny of actual remains.

At the present time the ancient theatre is the subject which is undergoing critical examination. It would be more exact to say it is the ancient stage. All of us have been puzzled in our school days by what we were told about the performance of a Greek play. It was easy to understand that the theatre resembled an old quarry, that tiers of seats were excavated, and that the plan was semi-circular. The approaches or climakes were few, and if a man were late he found it difficult to find a seat, and hence the impressive story of the Spartans all rising to facilitate the old fellow who was allowed to stumble among the Athenians, and his exclamation that some races talked about courtesy, but the Spartans practised it. Other legends also arise which were dear to youth, for they partly compensated for the dreaded consequences of an imperfect understanding of the plan. The fact was, the plan of the Greek theatre could not be made to agree with any of the buildings which were visited, as a matter of course, during Christmas holidays and furtively on other occasions. What became of the pit? You might come into the hands of one master who informed you it was entirely occupied by the orchestra, in which supernumeraries such as singers, musicians and dancers appeared, and sometimes the oracular chorus. But another master would say the orchestra was only a strip of space corresponding with the modern well for musicians, while in front of it, but several feet higher, was the forward stage or proscenium. The grave and reverend chorus would therefore have to tuck up their skirts and ascend a steep approach to the stage, a journey which would appear to affect their dignity and respectable appearance.

About the year 1841 an attempt was made by order of the then scholarly and mystic King of PRUSSIA to have the problem solved in the theatre of what is called the "Marble Palace" at Potsdam. The whole pit was treated as the orchestra. The chorus displayed their wisdom in it until the time came for their appearance on the stage, which they ascended in sight of the audience and afterwards descended by the same steps. The play selected was the "Antigone," and in Dublin the Potsdam example was soon afterwards imitated, and a worthy representative of the heroine was found in the present Lady THEODORE MARTIN, but we believe the pit was not sacrificed in order to give a semblance of antiquity to the performance. In Edinburgh the drama was also revived, but was confined to the stage. Acting on the advice of scholars, MURRAY, the manager, brought the painted scene close to the footlights. DE QUINCEY, who was present, wrote some severe remarks on the absurdity. Instead of in a hall at Thebes, the action appeared, he said, to take place in the boudoir of ANTIGONE. Another feature in the Potsdam revival was the letting down instead of raising of the curtain, and the novelty excited surprise. But the palace curtain was of no great width, whilst a curtain on the Greek stage would have to be sometimes 200 feet across. That was not the only part of the arrangements which was inconsistent with the antique practice, and for our part we have never witnessed a revival of a Greek play which appeared to be convincing about the similarity to the original representation.

For several years WILHELM DÖRPFELD, the German architect, has been pondering over the mystery of the orchestra among the ruins of Athens and of other Greek cities. He has come to the startling conclusion that there was neither skene nor paraskenion at a higher level than the orchestra. His theory is that the *dramatis personæ*, as well as the chorus, appeared on the orchestra level. A Greek play would therefore have some affinity to the "scenes in the circus" which are familiar to visitors to foreign hippodromes. Anyone who has witnessed such a drama as "Nero" and others of its class abroad will allow that as much dignity and tragic seriousness are attainable as would be needed for the production of a Greek play. According to the plans usually given, the Greek stage was a mere strip of platform before a wall, a small segment of the circle which bounded the orchestra. Some authorities say there was an altar in the centre of the stage, which would diminish the space available for actors and chorus. We may grant that the Greeks did not need for their tragedies such an area as is required in every modern theatre. But, on the other hand, space is an element in effect. It is impossible for modern actors to be pathetic when they are cabined, cribbed and confined, and dare not shrink backwards through fear of collision with a canvas. The late CHARLES MATHEWS made one or two experiments of carrying on the action of a little comedy by appearing before the curtain, but with all his delightful jauntiness the innovation did not succeed. Imagine a Greek tragedy

> In sceptred pall come sweeping by,
> Presenting Thebes' or Pelops' line,
> Or the tale of Troy divine,

under similar conditions of space, and it is difficult to understand how men's souls could be harrowed up with the spectacle. We can realise that a skilful burlesque writer like ARISTOPHANES could use the narrowest proskenion with advantage, but his plays are not the most typical examples of the Greek drama.*

Ordinary playgoers will, of course, agree with Herr DÖRPFELD, and although the pit will not appear equal to a modern stage for dramatic representations, yet of two evils they will take the lesser, and prefer a pit to a stage that, at its best, could not have surpassed the outer platform of a show at a fair. But German scholars of the old school cannot easily be persuaded to surrender the antiquated conclusions. The subject is one which rewards research, and countless quotations have been brought forward during the last couple of years to overcome the architect. It has to be admitted, however, that the original conditions of the Greek theatre did not comprise a dual stage at different levels. The waggon of THESPIS was of simple construction. The dances and hymns in connection with religious festivals were gone through on the ground around a temple or on the platform. When in the course of time people were attracted by dancing and singing, as if they were something else besides aids to devotion, the seats were arranged around the chosen spot for the performances. As long as dancers and singers remained in the inner circle or pit, and there was, it is believed, an altar or stand (thumele) in its midst, near which actors would congregate, all the spectators could see and hear. But with such a stage as appears in books about Greek theatres many of the people present who were seated at the sides were unable to see the actors, and those in the middle blocks must have found a difficulty in hearing, unless the masks produced the same sonorous effect as the sailor's speaking trumpet. Let the Greek theatre be considered as resembling the modern hippodrome, with rows of seats gradually ascending, and the pit used for performers, then many of the difficulties to an appreciation of the ancient drama would be removed. The skene and paraskenion could be reserved for gods and goddesses whenever they were introduced. We remember once at a performance of "Macbeth" seeing the three witches in a gallery of the hall of Glamis Castle as soon as the Thane appeared after murdering DUNCAN, and although not authorised by the text, the novel and impressive effect almost excused the innovation. In the Greek theatre there would be more of a warrant for having divine beings apart from mortals.

It may be objected that what is said by VITRUVIUS about the construction of the Greek theatre is evidence of the existence of an elevated stage. But we must remember that VITRUVIUS was likely to be better acquainted with Roman than with Greek theatres. Moreover, in his time the drama had to subject itself to the universal law of development, and differed much from the plays which were witnessed by free Athenians. The stage that is required for a comic opera in Paris when a division of the French army is welcomed by the crowds of an Italian city, would have to be diminished to a fifth or sixth of its depth to allow "Berenice" to be performed in a suitable manner.

* In *The Architect*, May 22, 1896, a small reproduction is given of the *plafond* in the Court Theatre, Vienna, which has for subject the performance of an antique play on an elevated platform in a Greek theatre, but under ideal conditions. The painting demonstrates that the actors dare not move backwards or forwards. They could only "close up" right or left on the same plane, or stand in one position as if representing a relief with coloured figures.

To describe the stage in RACINE'S day as necessarily corresponding with the stage of the Châtelet would, therefore, be absurd. PLINY is puzzling when he writes about theatres and other buildings, but he is exceeded by VITRUVIUS, who will never be comprehended until a special glossary is compiled for his architectural treatises. As to ruins, there is not one of a skene which dates from the time when the Greek drama was a sort of living force; and WILHELM DÖRPFELD, although he has considered the adverse arguments, need not fear he will be refuted by any masons' work now known to archæologists.

There is another argument in favour of his conclusion, which, as far as we know, has not been sufficiently utilised. What was the use of the cothurnus? To give height to the actors, it will be said. With an elevated stage the actors did not need to be stilted. But in the orchestrion it was an advantage to be slightly raised, for even an inch counts with a pittite when seen from above.

The great objection to Herr DÖRPFELD'S theory is that in the Greek drama the chorus is often supposed to be invisible, and the effect was aided by keeping the performers apart from the chorus. But it is impossible to respect that principle on all occasions. In the Parthenon frieze a part consists of gods and goddesses, who are believed to be those who looked down on the Athenian youths and maidens with affection. But they are not placed at a higher level, as if they were on Olympus. To the Greeks it did not matter that the gods seemed amongst the processionists. They accepted the limitations of the sculptor's art. The spectators of a drama were not likely to be less imaginative. With all our scientific realism, modern theatre-goers can be trusted to accept as a fact that the guests of MACBETH do not see the substantial figure of BANQUO, who is seated amongst them, or that GERTRUDE OF DENMARK is blind to her first husband, although he wears shining armour. If the chorus kept to the sides of the orchestra or ranged themselves around the outer circumference, the central space could then be occupied by actors who would easily be imagined to have eyes which did not see when the occasion required.

It would be folly to deny the existence of skene and paraskenia in the antique theatres. Any one who has been fortunate enough to see the massive wall at Orange can have no doubt on the subject. At all times it was necessary to have enclosures for the preparation of performances. Mr. PUNCH himself, with all his modernity, has to conceal himself and his victims for a time from his admirers. A circular theatre also becomes tiresome, for the eyes of the spectators cannot be always going round and round; they require a termination. That was supplied by the proscenium wall, and as it could be hung with tapestry or other drapery the vision would be gratified by resting on it. PLINY speaks of the scena in one place as if it were only a gallery for the exhibition of sculpture. In the theatre of SCAURUS at Rome there were, according to him, 300 columns and 3,000 statues on the skena. The actors were not to be envied who had to mix with so many figures, but so large a collection would have an attraction for spectators. What PLINY also records about glass or mosaic forming part of the proscenium wall is also evidence—although weak enough on account of the authority—about that part being an architectural background. As we have said, the elevated platform might be reserved for a peculiar class of characters. There must, we suppose, be always doubts on so important a subject, but Herr DÖRPFELD'S theory helps to remove some of those which are hindrances to the study of the Greek drama, and for so much he is deserving of the thanks of architects. Moreover, if we believe that tradition is in error in what is handed down about theatres, we may also become doubtful of similar statements about other varieties of buildings. In fact, it is always prudent when studying architecture to be doubtful about authority and to trust to the evidence of our own eyes.

The Plans of the new police station and sheriff court-house, which are to be erected at the corner of Church Street and George Street, Dunoon, have been passed. The buildings are in a free treatment of the Renaissance, and when completed will form a handsome addition to the town. The architect is Mr. William Fraser, Dunoon and Glasgow.

THE WEALD OF ESSEX.

PRIOR to the Christian era tradition tells us that Essex was peopled by the Euskardians, and then by the Celts. In the year 55 B.C. it was occupied by the Belgic tribe of the Trinovantes, and it was at the suggestion of Mandrubatius, a prince of the Trinovantes, that Cæsar invaded the country. For a time the Britons merely paid tribute to Cæsar, but a fresh invasion under Claudius took place A.D. 43, and the Britons were entirely routed. With the subdivision of Britain by the Romans, Essex was included in Flavia Cæsariensis, and contained five principal stations—Durolitum, Cæsaromagus, Canonium, Camulodunum and Ad Ansam. Camden fixed the site of Cæsaromagus in the neighbourhood of Brentwood, but it is generally supposed to have been near Chelmsford. The single-ditched circular camp of seven acres, of which faint traces can be seen at the south-west verge of Weald Hall Park, is regarded as a summer camp or Castra Exploratum of the Romans. With the exception of two Lares or household gods dug up at Shenfield, scarcely any Roman remains have been found in the district. The kingdom of East Seaxa was established about 527. In 870 the Danes first penetrated into Essex, and Saxons, Danes and Celts in turn held sway. In 1041 Edward the Confessor restored the Saxon supremacy. He died in 1066, and Harold, son of Earl Godwin and Governor of Essex, took possession of the throne. Four years previously Harold had founded a college for a dean and twelve secular canons at Waltham, and in due time he endowed it with South Weald, Brentwood and other manors. The Duke of Normandy, whom it is stated Edward had nominated his successor, landed at Pevensey, killed Harold at the Battle of Hastings, and ere he fully asserted his authority as King of England resided for a brief term at Barking Abbey. The manors William had seized he distributed among his followers, and Brentwood became the property of the De Wochendons. In 1120 Richard Bedumes, Bishop of London, founded an abbey at Chiche for twenty Augustine canons. It was dedicated in honour of St. Peter, St. Paul and St. Osyth, and endowed by William de Wochendon with the Manor of Brentwood. In 1221 David, Abbot of St. Osyth, having regard for the souls of his tenants at Brentwood, obtained the approval of Eustace de Fauconberge, Bishop of London, and the permission of Robert Parsons, vicar of Welda, to construct a small chapel at Brentwood, which was dedicated to St. Thomas à Becket, who had been murdered in 1170. No baptisms or burials were to take place there; no Mass was to be said on Sundays, and nothing was to be done to injure the mother church, to which two pounds of wax was to be given yearly as tribute. Roger of Wendover, in his "Flowers of History," tells how Hubert de Burgh, the favourite minister of Henry III., having evoked the King's displeasure, fled in fear to Brentwood, and sought sanctuary in the little chapel. By order of the King, the Sheriff of Essex blockaded the chapel, and in due time De Burgh was starved out and taken in triumph to the Tower. He eventually made his peace with the King, and died a natural death. Thirty years ago the chapel was standing; it was constructed of flint and pebbles, was partly Early English, but mainly Perpendicular. It consisted of a nave and chancel, with tower and spire at the north-west angle and a north porch. There was a double piscina on the south side of the chancel and a single one on the south side of the nave. For a time it was used as the boys' national school; to-day a truncated tower and arch is all that remains. The new Gothic church of St. Thomas the Martyr is of white brick and was built in 1835. The apsidal chancel is a later addition; it contains a small brass to John Parker, 1672, and two pieces of heraldic glass removed from the old chapel.

In the great Forest of Essex clearings were made by fire and other means, and gradually villages and towns were formed. Welda, the wood, was one of these now known as South Weald to distinguish it from North or Bassett Weald in the same county. Another was Brentwood, still locally known as Burntwood, and mentioned in ancient documents as Boscus Arsus and Bois Ars. Shenfield was another, and here we notice how, lacking stone, of which the county is remarkably deficient, wood was used in the construction of churches. At Greenstead is the little church with the wooden walls where the body of St. Edmund rested in 1013; at the beautiful church at Saffron Walden a wooden aisle was destroyed by fire in recent times; at Shenfield are a wooden aisle and tower almost intact, and at Blackmore, Margaretting and Stock the wooden towers of the churches still remain. Although Shenfield may have had a little wooden church as far back as the days of the Confessor, the clustered columns of the oaken piers only take us back to the fifteenth century, and the embattled brick doorway at the west end of the north wall is obviously of Tudor date. The register commences in 1538 and the marble altar tomb with effigy of Elizabeth Robinson, of Gwersilt, Denbigh, is dated 1652. The pseudo-restorer came in 1853 and ten years later, and in the dark grey rough-cast coating of the church and in the rechiselled mouldings and window tracery his hand is seen.

Adjoining the churchyard on the north is the gabled Elizabethan manor house. In the fourteenth century it belonged to Thomas of Woodstock, the sixth son of Edward III. In the next century it was owned by Humphrey, Duke of Buckingham, who lost his life at the battle of Northampton. It was then seized by Edward IV. and settled on his Queen, Elizabeth. It ultimately passed to the Lucas family and gave title to Baron Lucas of Shenfield. By the marriage of his daughter it passed to the Duke of Kent, and in the eighteenth century it was conveyed by marriage to the Earl of Hardwick. The present proprietor is the Countess Cowper.

South Weald, or Southwold Church, dedicated to St. Peter, is unique in Essex as being the church furthest from the sea that has a ragstone tower. The tower was erected about 1485, but only the lower portion remains; the upper part with some other interesting features of the building were swept away some thirty years ago, when the church was rebuilt by Mr. Teulon, but it is satisfactory to note that the Early English arcade and the Norman doorway, with its chevron mouldings and reticulated pediment, were re-erected in their original places. The font dates from 1662, and a small brass of 1567 bears an inscription to Sir Anthony Browne, of Weald Hall. The hall is interesting as having been for some time the residence of Queen Mary, when Princess. The present owner is Mr. C. J. H. Tower. In the adjoining estate of Rochetts, in a little chapel since converted into a gardener's lodge, it is stated that Mary attended Mass. Rochetts was the favourite residence of Earl St. Vincent, who died there in 1823.

Sir William Petre, Knight, LL.D., was one of the principal Secretaries of State in the reigns of Henry VIII., Edward VI, Mary and Elizabeth. It has been stated that in Henry's time he observed the King's humour, in Mary's time he minded State affairs, and in Elizabeth's he was religious. At the dissolution he devoted his wealth to the purchase of monastic lands, and from Pope Paul he obtained a grant to secure them to his heirs for ever. His son John was elevated to the peerage as Baron Petre of Writtle on July 21, 1603.

Among the estates which Sir William acquired was Thorndon Hall, which he purchased of Sir John Mordaunt. A century before it belonged to the family of FitzLewis, and John, the last of the line, had married the daughter of Sir Robert Lovel. Great were the rejoicings on the wedding day, but in the stillness of the night a fire destroyed the old hall, and bride and bridegroom perished in the flames. The present white brick mansion was built by James Paine about 1770. The hall consists of a large block and two wings, connected by semicircular corridors. The style is Classical, in vogue during the last century. The roof of the hall, some 40 feet square, was supported on eighteen scagliola columns; the saloon was 60 feet by 30, and the drawing-room 38 by 26. George III. and Queen Caroline stayed there in 1778 on their way to the great review on Warley Common. The visit was used by Gilray for the subject of one of his most popular caricatures. History repeats itself; and in March 1878 a fire broke out in the hall, and only the right wing was saved. The shell, however, has been carefully preserved, and every one must congratulate Lord Petre on having now commenced its restoration. In the right wing is the private chapel with David's *Nativity* above the altar, and in the gallery, among other pictures, are portraits of Sir William Petre and the Duke of Norfolk, by Holbein; and Mrs. Onslow, by Cosway. There is also a portrait and some relics of Lord Derwentwater, busts of Fox and Lord Petre, and some valuable illuminated manuscripts. The park is two miles long, is the largest and most beautiful in Essex, and is well stocked with deer. On the edge of the wood is the Gothic mortuary chapel, built of white stone, carved and embroidered. The present owner of Thorndon Park is Bernard Henry Philip Petre, fourteenth Baron, formerly lieutenant of the 1st battalion of the Lincolnshire Regiment; he is co-heir to the Baronies of Howard and Greystone.

The Reformers had made their mark at Brentwood, and firm in the Protestant faith was a family named Hunter. The one son, Robert, remained at home with his father; the other one, William, was apprenticed to Thomas Taylor, a silk weaver in the City. With the crowning of Mary the doctrine of Transubstantiation was enforced, and the parish priest of St. Katherine Colman commanded William to attend the Easter Mass. William refused, and his master dreading the consequences of harbouring a heretic, commanded him to return to his father. In the little chapel at Brentwood he was found by Father Atwell committing the grave offence of reading the Bible. The Vicar of Southwell, as Foxe spells South Weald, was fetched, and William was taken before Justice Browne, who sent him to Bishop Bonner. For two days and nights he was kept in the stocks, he was loaded with irons and cast into prison, where he remained nine months. Bonner had promised him the freedom of the City and forty pounds to set him up in business, and had even offered to make him his house-steward, but nothing would induce him to recant. He was duly tried, imprisoned in Newgate, conveyed to Brentwood, and there, at the age of nineteen, was burnt under the Martyr's Tree on March 26, 1555, in the presence of good Sir Anthony Browne, the justice. Two years later Sir Anthony built and endowed the Grammar School at Brentwood, and by purchase from Sir Brian Tuke, of Layer Marney, he became lord of the manor of South Weald, where he erected some almshouses. In 1558 he was appointed Lord Chief Justice of the Common Pleas, and Elizabeth permitted him to hold the office of puisne judge. He died in 1567, and in the parish church an altar tomb was raised to his memory. In 1588, on her way to Tilbury Fort to deliver her Armada speech, good Queen Bess rode through Brentwood, and as the people shouted and waved their hats, how many of them thought of the boy martyr who perished under the elm by which she passed? In the good old days, forty coaches passed daily through Brentwood, then the assize town; but the Crown Inn, of which Salmon wrote, has disappeared, and the White Hart, with its galleried courtyard dating from the fifteenth century, is without a horse in the stable. The clatter of the coach has given place to the bell of the bicycle, and the cheering sound of the post-horn is succeeded by the din of the Salvation Army drum. So fades the glory of the Weald.

ARTISTS' COPYRIGHT.

THE following evidence was given on the 7th inst. before the Select Committee of the House of Lords appointed to consider the law of copyright.

Mr. H. T. Wells, R.A., said that after the report of the Royal Commission in 1878 the Royal Academy drew up a memorial with regard to copyright in works of art. He took a large share in drawing up that memorial, a copy of which was sent to the Prime Minister, to the Queen, and to every artist who could be reached. There was absolutely no dissension among artists as to the contentions of the memorial. He had had nothing to do with the preparation of the Artistic Copyright Bill (1898) presented by Mr. Bale, but he thought it was based on the suggestions made by the Royal Academy and would meet their wishes. The view of the Academy was that the common law right of the artist in his works should be embodied in an Act of Parliament, and should in some respects be strengthened. Artists desired that the copyright in their work should date from production and not from publication. Moreover, it would be absurd to make any restriction as to the place of an artistic production by a British subject or one domiciled in the British dominions. As to the duration of copyright, the Academy accepted the period suggested in the report of the Commission, namely, thirty years after the death of the author of the artistic work. With regard to registration, he was strongly of opinion that there should be no registration unless there had been an assignment of the copyright.

By Lord Monkswell: He would be extremely astonished if artists objected to exhibition constituting publication, if copyright were only to be obtained after publication. The great difficulty was that the majority of pictures were never published, and would therefore be cut off from copyright. He very much preferred clause 2 of the Artistic Copyright Bill to that of Lord Herschell's Bill. The Royal Commission reported against the expedient of drawing any distinction between portraits and other pictures, and it would certainly be an odd thing in England to put this disability on portrait-painters, having regard to the position which English portraiture had taken in the word.

Lord Knutsford: But if a man commissions an artist to paint his portrait and pays him for it, why should the artist have the copyright?—If the picture had been a landscape the artist would have the copyright, why not when he paints a portrait? All the Bills which had been drawn gave the copyright in a picture to the artist, unless the picture was a portrait.

Lord Thring: Do you mean to say that at common law the purchaser of a picture does not acquire copyright?—Certainly not.

Lord Monkswell: You would rather that there was no copyright in a picture, and that every one, including the artist, should have power to reproduce it, rather than that the right of reproduction should be confined to the purchaser of the picture?—Yes, especially with regard to portraits.

By Lord Crewe: The owner of a picture ought to be protected against replicas of the same size and in the same material as the original. When an artist produced illustrations for a book, he ought not to be allowed to reproduce them in the same form separately and in rivalry with the book; but there should be nothing to restrain him from developing the idea.

Lord Knutsford: Should living pictures be an infringement of copyright?—Yes, I am very decided as to that.

Mr. Briton Riviere, R.A., said he was one of the representatives whom the Royal Academy wished to give evidence upon the question of copyright in artistic productions. The Royal Academy had nothing to do with the Artistic Copyright Bill

of the present session, but they approved generally of its provisions. As to copyrights dating from publication, the whole artistic profession felt very strongly that copyright should date from the act of creation. The definition of publication as "public exhibition for reward or the first offering for sale or hire" would not only present great difficulties to men in the ordinary groove of artistic work, but would be absolutely fatal to some outside that groove. Some eminent artists would never get copyright at all. For example, Rossetti never exhibited in public; Sir E. Burne-Jones, before the Grosvenor Gallery was opened, confined his works to his studio; and Turner, in regard to the works which he intended to leave to the nation, refused altogether to offer them for sale. He would not deprive a man of copyright because he published first outside the Queen's dominions. Subsection 2 of Clause 19 (which gives the exclusive right "to publicly exhibit the work or any copy thereof, or any representation thereof, or of any part thereof") would bring divided interests under one head and make the ownership of a picture a very uncertain thing indeed. Many exhibitions would be impossible under this clause. For instance, Sir Henry Tate's gallery would certainly not be able to remain open, because he was probably not the owner of any of the copyrights in the pictures contained therein. The owner of a picture would be compelled to confine that picture to his own house. The copyright in a picture was valuable to somebody who had nothing to do with the picture itself, simply for purposes of reproduction.

Lord Thring: I am a governor of Holloway College, where we have a very splendid collection, especially for educational purposes. If this clause passed, we would not be able to keep it open?—That is so. As to clause 20 (title to copyright in artistic works made on commission), witness said it was of vital importance to artists, and upon grounds which everyone acquainted with the methods of reproduction must accept. In any form of reproduction the artist's reputation was at stake from beginning to end, and he alone could tell how the thing should be done. He ought to be the one to choose who should be the engraver and what should be the process. Even at the hands of an eminent engraver, without constant advice and sympathetic supervision by the artist, a work could not be rendered in an absolutely satisfactory manner. The late Lord Leighton took a great interest in this question, and drew up a clause to protect the rights of the owner of a portrait, for it was only in portraiture that there could be a question of other interests being at stake than those of the artist. Lord Leighton suggested that no copies or engravings from a portrait should be sold or exhibited without the sanction of the person who ordered such portrait. Such a clause the whole profession would accept. But he would not say that the copyright of a portrait should vest in the person who gave the commission to paint it. Some of the greatest engravings which we had in this country, which continued to increase in value, were from portraits, and the engravers could never have carried their work out if the copyright had not from the first been under the control and supervision of the artist. In regard to all subject pictures, this was of such importance that no more alarming proposal could be made than that copyright should go haphazard into the hands of the owner of the picture. The word "commission" was very difficult to define in the artistic profession, but the man who gave a commission for the sake of acquiring a copyright could always guard himself at the time, and the artist could always guard himself; but if the mere giving of a commission were to confer the copyright the quality of engraving and reproduction would be placed in a very dangerous position. He had never had any difficulty himself with the owner of a picture, and practically the owner had the right of veto on reproduction, because he could refuse access to the picture. But of course the development of photography had made the owner's veto in that respect less absolutely effective. In no circumstances should an artist be allowed to produce a replica of the picture he had sold of the same size and in the same material as the original. The etiquette of the profession would forbid that already, but it might be done under the law. The words "main design" were only acceptable to the artist because they implied that the constituents of the picture were not to be put together again so as to reproduce the original motive. As to clause 22, dealing with the illustration of books, it should be provided that the publisher should not be allowed to reproduce them apart from the context for which they were designed, except in case of special agreement. The artist, moreover, should not be able to reproduce the illustrations in the same size and form as in the book.

Lord Thring: Could not the clause be cut out and all these things be left to private arrangement?—There would be no objection to that.

Witness added that he felt very strongly that a clause should be inserted to protect the artist from a change in the title of his work. The artist usually took great care in the selection of the name of his picture, so that it should express just enough to make the purpose of the picture clear. The work might fall into the hand of someone who was insensible to the artist's intention, and by a change of the title adapt it to some other purpose. That change ought to be an infringement of copyright. For example, a stupid person might get hold of Millais's "Huguenots," and by calling it "The Lovers" destroy the whole sentiment of the picture. The artist's name should not be put to a subject which was not his own.

Lord Monkswell: In the case put, the artist has parted with his copyright, and therefore the remedy would lie outside the copyright law.

Lord Thring: You might get an injunction, but it would not be under the copyright law.

Mr. Bulmer Howell, representing the Photographic Copyright Union, gave evidence on Monday in support of the clauses dealing with copyright in artistic productions. With regard to the question of title to copyright in artistic works made on commission, the sub-committee which drafted the Bill thought it fair that the person who gave the commission should in the first instance be the owner of the copyright. In this respect they differed from Mr. Briton Riviere's evidence. He should have thought that Mr. Briton Riviere's objection would be met by the fact that it was always competent to the artist to insist upon an agreement in writing which would give him copyright in his work. In the committee he did not hear strong objection taken to the clause, although artists were present; and, indeed, he had been under the impression that the clause was not objected to by any member of Mr. Murray's committee. With regard to photographs, the clause was intended to cover the case where a photograph was taken by an employé of a firm like the Stereoscopic Company, it being provided that in such cases the copyright in the photograph should belong not to the employé but to the company which employed him. The Photographic Copyright Union were most anxious not to impinge on the rights of artists; on the contrary, they were interested in preserving them as far as possible. Asked by Lord Thring as to who was really the author of a photograph, the person who arranged the camera and the sitter, the person who took off the cap, or the person who printed, the witness replied that he should designate the author to be the man who posed the sitter and took the most active and artistic part in the operation. He mentioned one curious anomaly, which he hoped might be removed, namely, that while books were protected in every colony artistic works were protected in none.

The committee adjourned.

STRATFORD-ON-AVON CHURCH.

THE church of Stratford-on-Avon—Shakespeare's church—has been reopened after being closed for six months. The committee, under the advice of Mr. Bodley, started with the intention of improving the organ, renovating the interior of the nave and rebuilding the old vestry. It was computed that this would cost 5,000*l.*, viz. 800*l.* for the organ, 1,000*l.* for the vestry and the rest for the nave. The last, as the most extensive, was to include a new warming apparatus, a new floor, new oak benches, a new pulpit and electric lighting. The committee began with the impression on their minds that there would be no difficulty in raising money for Shakespeare's church. But they were soon undeceived. Money has not come in, and the result is that not only has a good deal of the work contemplated not been begun, but also that a rather formidable debt remains on what has been done. What has been completed is as follows:—The organ has been greatly improved, an excellent warming apparatus has been introduced, the floor has been entirely relaid, partly with stone, partly with oak blocks, and half the oak benches needed have been provided.

The cost of these improvements has been, in round numbers, 3,000*l.*, and towards defraying it the committee have received a little over 1,200*l.* Of this only 296*l.* has come from outside the parish, and much of this from immediate neighbours. The committee have been disappointed of any help from America.

The result is that the church now has only half its seats provided, it is without a pulpit and without a vestry.

The Nurses' Home, Ashton-on-Mersey, near Manchester, which has been erected from the designs of Messrs. Whitelegg & Whittaker, architects, of Brazennose Street, Manchester, at a cost of about 1,000*l.*, was formally opened on the 9th inst. by Mrs. Coningsby Disraeli. This institute contains two wards (each for two patients) on the first floor and an accident ward on the ground floor, with accommodation for the nurses. It is built in the half-timber style with tiled roof, and immediately adjoins the St. Mary's schools, which were designed by the same architects, and opened a short time ago. Mr. John E. Dean, of Ashton-on-Mersey, was the builder.

NOTES AND COMMENTS.

THE concession of a colonial penny postage suggests that the authorities of the Post Office are gradually learning that something else is expected from them than a balance sheet showing a profit. At present there are apprehensions of interference which are fatal to improvements in envelopes and post cards such as are common in other countries. Some of the foreign post-cards may be called works of art, and they have to be prepared by young artists or photographers, who may be considered as artists. But English stationers say that similar productions would not be considered as complying with the official regulations in this country, and they will not make the experiment of competing with foreign manufacturers. The British Consul in Frankfort says that the pictorial post-cards posted from spots frequented by visitors is enormous. In a single season there were 148,000 from the Kyfhäuser monument, 128,000 from the national monument on the Niederwald, 36,000 from Heidelberg Castle, while the cards posted from the Berlin Trade and Industrial Exhibition were over a million, and from the Hamburg Floricultural Exhibition 572,000. This new trade not only affects the Post Office, but also the paper industry and those concerned in illustrating, as well as various branches of the stationer's trade. Elegant albums are made for collecting these souvenir cards, and are favourite presentation articles. Quite recently the Government of Saxony offered a prize for the best series of about twenty souvenir post-cards with views of Saxony, and German manufacturers have assisted the fashion by producing handsome cards in the greatest possible variety. The Consul-General fears that German exporters will monopolise the manufacture and sale of these cards in Great Britain unless British manufacturers take up the matter promptly. The trade in illustrated memorials is proportionately as great in Holland. But if British manufacturers hesitate it is owing mainly to the wide-spread conviction that the Post Office will not tolerate anything on a card but a few lines in type or writing. A scrap from a newspaper pasted on a card as a substitute for writing will not be passed, and naturally it is concluded that a miniature photograph is also illegal.

THE part of the esplanade of the Invalides, in Paris, which will be occupied by the four palaces assigned to various industries and decoration for the Exhibition of 1900 is now surrounded by a hoarding. The architects who were fortunate in obtaining the commissions for the buildings are MM. TROPEY-BAILLY, TOUDOIRE, ESQUIÉ and LARCHE. The first is the oldest, but he is only fifty-two. Hitherto he was not engaged as architect in public buildings. He is one of M. VAUDREMER's pupils. M. TOUDOIRE, who is six years younger, is architect to the Lyons Railway Company. He is a pupil of M. QUESTEL. M. ESQUIÉ, a pupil of M. DAUMET, is forty-five, and has charge of the Arc de Triomphe and the Vendôme Column. He is also a professor of architecture, and designed some large buildings in the provinces and abroad. M. LARCHE is forty-three, and a pupil of M. GUADET. He has had the novel experience of obtaining second prizes in five competitions—among them were the Sorbonne and the Opéra Comique—before he was successful in the competition for 1900. He has co-operated in the erection of the Hôtel des Postes and the Monte Carlo Casino.

IT is expected that the report of the select committee on the museums of the Science and Art Department will contain a recommendation that the duties of the "art director" should be greatly restricted. In the former inquiry it was shown there was much indefiniteness about the arrangements for the purchase of objects for the South Kensington and other departmental museums. Hardly two of the witnesses agreed about the extent of their powers or their responsibility. The art director, who was supposed by one theory to be the ultimate referee on all questions of buying works of art, was also expected to control the teaching in the art classes. It is now suggested that the museum director should be entrusted with the purchases on behalf of the Museum, but he is to consult in every case with whatever keeper possesses the expert knowledge that will secure the Department against the skilful forgery and sophistication of art objects. The director for art will consequently be concerned solely with the supervision of the art schools and classes. Some arrangement of the kind is demanded, for it cannot be said that either the additions to the Museum or the improvements in the schools are as satisfactory as from the outlay on them would be expected.

THE novelty of having two salons which could be visited for the franc which in other years was paid for admission to one of them naturally attracted this year large crowds to the Champ de Mars. The amount received during the two months the exhibition was open was 348,000 frs., or, in round numbers, 14,000*l.* Strange to say, the Sundays were most profitable, although they were free in the afternoon. As many as 30,000 visitors passed through the turnstiles on one Sunday. The receipts will be divided in the proportion of two-thirds to the older salon and one-third to the new. That the usual visitors were exhausted is evident when it is said that on the last day only 3,000 francs were received, although it was known the money was to be applied towards the purchase of examples for the Louvre collections.

ILLUSTRATIONS.

CATHEDRAL SERIES.—PETERBOROUGH: EAST END. TRIFORIUM.

MORLEY HOUSE, ST. MARGARET'S BAY, DOVER.

THE stonework shown in the illustration of the above, together with the copings and pier-caps to boundary walls and carriage entrances, was executed in patent Victoria stone of a colour equal to the best yellow Mansfield, and the work has an appearance of the natural stone itself. The spandrels and panels were carved as natural stone, and have a very sharp appearance, as can be seen by the illustration. This material has been proved to successfully withstand the strong sea-air of our coasts, hence its application here. Mr. G. D. STEVENSON is the architect.

PROPOSED MEMORIAL SCHOOLS, ST. MARY OF THE SEA, HASTINGS

THESE schools are to be built as a memorial to the late Dr. FAA DI BRUNO, author of "Catholic Belief," the present schools, which are in the crypt of the church, being inadequate for their purpose. Accommodation will be provided for eighty infants on ground floor and eighty girls and eighty boys on first floor. An assembly hall is on ground floor with platform and retiring-room for performers, with cloakrooms and lavatories leading from staircase landing. The external walls are of hollow brick with Bath-stone dressings and mouldings, with hard York for copings, crosses, &c. Westmoreland green slates are used for roof. Inside the classrooms will have glazed brick dadoes and walls above plastered. Ground floor classrooms and assembly hall 1½-inch wood-block flooring. The cost is estimated at about 2,600*l.* The architect is Mr. J. H. EASTWOOD, A.R.I.B.A., 42 Cheniston Gardens, Kensington, W.

PROPOSED NEW ROOF AND DECORATION TO THE GUARDIAN ANGELS' CHURCH, MILE END.

THE nave of this church is at present 36 feet wide, 24 feet high and 63 feet long, with a flat ceiling over same. Consequently the interior presents a poor appearance. It is also badly constructed, insufficiently lighted and ventilated. The illustration shows a new roof, the construction of which is formed of four arched steel lattice ribs secured to eight steel stanchions, dividing the nave into five bays, reducing the width to 23 feet 9 inches and raising the height to 33 feet, and forming aisles on each side. The lattice ribs and stanchions will be cased in fibrous plaster slabs and decorated.

The effect will be to produce an interior of better proportion, well lighted and ventilated by a row of clerestory windows on each side.

It is also proposed to build a new front towards the Mile End Road, lengthening the church by about 10 feet, and increasing the accommodation of sittings.

The cost of both above works is estimated at about 2,000*l.* The architect is Mr. J. H. EASTWOOD, A.R.I.B.A., 42 Cheniston Gardens, Kensington, W.

THE HIGH BUILDINGS OF THE ANCIENTS.

TO Professor Lanciani is due the credit of the discovery that there were building laws in Rome long before the Christian era. As the price of urban property increased the landlords were forced to build high, and 200 years before the time of Christ the height of Roman tenements became alarming to those having the care of the public safety.

There are frequent allusions among the Roman historians, orators and poets to the enormous height of the tenement buildings of Rome, but no definite figures are given until the days of Augustus, when a law was promulgated by the Senate which fixed the height of new structures at 60 feet on the street front, without making any allusion to the height of the rear. It is, however, known that in the rear these tenement buildings rose often several storeys higher than in the front, so that from a distant height, as from the top of a temple which commanded an extensive view, a row of tenement buildings in Rome presented the appearance of a terrace—highest in the rear and descending by storeys toward the front. This law of Augustus applied to new buildings, respect, then as now, being shown for investments already made. The number of storeys on the street front of these Roman buildings was generally ten to twelve, with fourteen or fifteen in the rear. The lowest storeys were 8 or 10 feet in height, but, from accounts given by the writers of that time, the storeys appear to have gradually diminished as their height above the ground increased, so that the topmost tenants lived in quarters where very often they could not stand erect. That the storeys were sometimes much less than 5 feet is shown by the discoveries in Pompeii, where in a house inhabited, presumably, by poor tenants, a storey of 4 feet 3 inches has been discovered. This was a living room, too, for in it were found all the articles which pertained to Roman housekeeping—cooking utensils, beds, stools, mirrors, combs, brushes and other things which, with the bones of the family, furnished indisputable evidence that the rooms had been occupied. It is quite likely that there were thousands of rooms in the tenement districts of Rome that were no higher than this Pompeiian tenement, and, indeed, more than one Roman poet alludes to the lodgings into which he must "creep," the word, perhaps, indicating not a figurative but a literal method of entrance. That the tenement houses of Rome towered at least 100 feet above the street in front, and probably 125 to 130 feet in the rear is certain, for the promulgation of an edict limiting the height to 60 feet in front indicates that this height had been so greatly exceeded in so many cases that the public safety was believed to be imperilled. How many storeys were contained in these tenements is conjectural, but if the upper storeys were no higher than that of the house in Pompeii, the Roman tenements may have contained as many or more storeys than the modern office building.

The height of these Roman buildings was entirely irrespective of the width of the street. Modern building laws have more or less reference to the width of the streets on which the building faces, and to the isolation of the structure or its proximity to other buildings. The Berlin Building Act admits in residence buildings a maximum height of 36 feet if the street is of that width, and a greater height if the street is broader; the Building Act of Vienna allows 45 feet if the street is that wide; while the building laws of Paris permit a height in residence buildings of 63½ feet, provided the street is of that width. The Roman building law, however, had no reference whatever to the width of the street, and as most of the Roman streets were very narrow, the city, looked at from a height, strongly resembled a mass of houses with narrow trenches between. Many important thoroughfares did not exceed 10 feet in width; the widest streets in Rome were not more than 100 feet, while the side streets were often mere passageways, from 5 to 6 feet in width. With streets no wider than this, and with houses of which the upper storeys projected farther than the lower, it was quite possible for the inhabitants of the topmost tenements to shake hands across the streets, if the custom of shaking hands had been as much in vogue then as now. That the situation was greatly to the advantage of thieves, marauders and night prowlers is evident from the frequent allusions to the depredations of burglars, and the ease with which a passage could be effected from roof to roof, even across the street. While providing an escape for night-hawks, the narrow streets proved also the salvation of tenement residents in case of fire. A city in which the houses were so closely packed together was extremely liable to extensive conflagrations, but when a tenement house took fire below the population simply climbed the stairs to the roof, and, with such of their goods and chattels as could be easily transported, escaped to the roofs of adjoining tenements or across the streets to houses not affected by the conflagration.

The extreme height and overhanging storeys of the Roman buildings were a source of danger to the citizens in more ways than one. There were many important thoroughfares in Rome that were always in the shade; only at high noon did a streak of sunlight find its way between the buildings to the pavement. The streets were thus always damp, for, although Rome was sewered and there was a penalty against throwing slops into the street, the city was none too cleanly, and there were frequent humorous allusions, among the poets and writers of odds and ends, to the misfortunes sustained by pedestrians, who, while passing along the street, were deluged by buckets of slops carelessly thrown from upper windows. Pliny mentions a wedding which ended in a riot on account of the leading participants being thus besprinkled with filth—not of design, but through the carelessness of a housewife who lived in the eighth or tenth storey, and had no desire to work overtime in walking up and downstairs with her bucket. The narrowness and dirtiness of the streets explain the frequent visits of various forms of pestilence, which from time to time devastated the city; the black death, the plague, the mysterious visitations of unknown diseases, which from their symptoms seem to have been akin to cholera, yellow fever and diphtheria—all these were indirectly chargeable to the high buildings and the damp streets.

There was another danger hardly less serious. Queer as it may seem to us in these days of gas and electricity, the streets of a city which certainly contained 2,000,000, and may have had 4,000,000 of population, were at night in the darkness of Egypt. Such a state of things presented singular facilities for the operations of footpads and highwaymen, and the frequency with which their operations were attended by murder is shown by the numerous epitaphs that have been discovered intimating that he whose ashes lay beneath was killed by robbers. Every householder, every tenant in a tenement house, had to look after his own security, and accordingly the doors of residences at dark were barred, every window was secured by a strong iron lattice, and in tenement houses the street doors were fastened and a common fund, raised by the tenants, was provided to secure the services of a watchman to look after the building. In the tenement structures which had a respectable class of tenants the watchman went his rounds through the building at regular intervals, but in the better class of houses there were generally two or more watchmen, and the one at the front door was chained so that he at least would give proper attention to business through the night.

Little heed seems to have been paid by the Roman builders to the edict of Augustus, and from all accounts the houses in the tenement district rose higher and higher, for in the next forty or fifty years half a dozen edicts were promulgated on the subject, which would not have been the case had the first been obeyed. Nero did more for Rome than any monarch before or after his day. Nero has probably been the most abused individual of ancient times, and his wanton cruelties, the barbarity with which he persecuted not only the Christians but all opponents, political or religious, his nameless vices, the murders of his relatives, chargeable to his account—all have combined to render him an object of detestation to succeeding ages. But, probably on the principle of "giving the devil his due," Professor Lanciani has shown that the merit of remodelling Rome was due to this monster in human form. If Lanciani is to be believed, the great conflagration which destroyed Rome in A.D. 64 was the work of Nero's agents, and if the latest researches are to be credited, the work was done with such effectiveness that of the fourteen wards three were completely burned, seven were almost totally destroyed, and the other four were more or less damaged. There seems, however, to have been method in the madness of the emperor, for some historians assert that in spite of the extent of the conflagration not a single life was lost, while others, admitting there were casualties, declare them to be very few.

However this may have been, it is certain that as soon as the ruins had grown cold the entire working population of the city was given employment in clearing off the *débris*, transporting it to the Tiber and erecting new structures. The imperial architects went to work and reconstructed the entire plan of the city. Without paying the slightest regard to previous lines, new structures were laid out as nearly straight as the nature of the ground would permit. Public squares, breathing spots, were located at convenient places in the tenement district, and a law was promulgated that no residence house should be higher than twice the width of the street. This seems to be the first reference among the Roman building laws to any proportion between the height of the house and the street. The changes proposed by Nero, had they all been carried out, would have made Rome a city which for comfort, convenience and safety was unequalled in ancient times, and not easily surpassed by modern cities. Every tenement house or residence building was to be isolated from its neighbours; wooden ceilings in the two or three lower storeys were prohibited, the ceilings rested on stone or brick arches, wood being permitted only in the upper storeys. Every householder was ordered to erect a wooden portico in front of his building that passers-by might have shelter from sun and rain, while the width of the streets and the isolation of the buildings furnished a reasonable guarantee against future extensive disasters by fire.

Very soon after the promulgation of this law Nero left Rome on his musical tour of Greece and the provinces, and his death in A.D. 68 put an end to the reforms which he projected. They were partially carried out, but his memory was so detestable to the Romans that even the excellent plans which his architects drew up for the reconstruction of the city were thrown aside because they were connected with the name of the most hateful tyrant who had ever occupied the throne of Rome. The old abuses returned, public squares were sold to speculators, tall tenements with narrow streets again came into fashion, and such was the height of the buildings that one Roman poet mentions a friend who had to climb 200 steps every night to get to his lodgings, while another alludes to a fire in a tenement which had reached the third storey before the dwellers in the upper portions of the building became aware of its presence.

The next building law in Rome was promulgated by Trajan, and without respect to the width of the street. It forbade a height in new buildings of more than 70 feet on the street front, like the other building laws, making no allusion to the rear storeys. The tenement evil in Rome was thus on the increase, and an explanation is found in the fact that in those days men were obliged to live close to their work. There was no rapid transportation which enabled the workman to live miles away from the factory, and to travel back and forth to his home morning and evening. The workman must live within an easy walk of the place of his toil, so the tenement districts of Rome were all located in the manufacturing quarters, and, to state the case in a modern way, all the tenement region of Rome was one vast sweating-shop.

Rome was not the only ancient city with building laws; Constantinople had them also. When the Emperor Constantine determined to erect his capital on the Golden Horn, the peninsula was separated from the mainland by a wall, and thus the limits of the city were defined by the imperial orders so that all might understand whether city taxes or country taxes were to be paid on property in the vicinity, for the difference between urban and suburban real estate was then as closely defined as now. As soon as the Emperor's intention became known there was a rush of speculators from all parts of the empire to purchase property in Constantinople and vicinity, and within a year after the imperial proclamation setting apart the peninsula as the chief city the property had gone up 300 per cent. All the real estate within the wall which Constantine had erected as the limit of the capital was held by speculators and capitalists, who invested hoping to realise a very large profit. Their expectations were not disappointed, but the change of capital from Rome to the East produced a result which was not anticipated.

The price of land rose so high that sufficient rentals could not be realised from the buildings already standing, and capitalists sent to Rome for architects to erect tenement buildings. They came, and if any judgment can be formed from the results of their labours, they must have come in considerable numbers, for in less than ten years after the announcement of Constantinople as the capital city the tenements of Byzantium rivalled the tenements of Rome. Constantine had fixed upon the top of the hill, the highest point of the peninsula, for his palace, but to the intense disgust of the royal occupant, it was discovered that before the splendid residence of the Emperor was fairly finished his view of the sea was cut off by the innumerable tenements which, standing on much lower ground, still rose high enough to impair the prospect from the royal palace. Constantine was not the man to put up with this sort of thing. He had spent too much money on his house to move, so a building edict was promulgated forbidding any tenement higher than 100 feet to be constructed, and also ordering those which exceeded that height to be reduced to the proper limit. Great was the outcry among investors and speculators, for it is said that from one block of buildings four storeys had to come down. How high these storeys were we have no means of knowing, but supposing them to have been only 9 feet, there must have been tenement buildings in Constantinople that exceeded 136 feet in height. Various emperors after Constantine endeavoured to restrict the construction of high buildings, in order to retain a view of the sea from the imperial residence, but all in vain; the architects persisted in carrying the houses up to the legal limit, and whenever it was possible to disregard the statute it was disobeyed.

One curious case is recorded of evasion, showing that men in those days were as sharp as they are now in ignoring the spirit, while pretending to comply with the letter, of the law. Apothagos, a Constantinopolitan, erected a row of tenements about halfway between the Golden Horn and the royal palace. The houses were of stone and brick up to the legal limit of 100 feet; above this there was erected a shanty structure of wood, three storeys in height. The imperial building commissioners objected and ordered Apothagos to pull down his superstructure, but he refused, alleging that the law applied to permanent, not to temporary, buildings; that the wooden superstructure was only temporary, designed for the use of his workmen until the interior of the house should have been fully completed. The commissioners persisted in their order for the removal of the wooden storeys, when the stubborn Apothagos went to law and applied to the imperial court for a writ commanding the commissioners to abstain from disturbing his peace and damaging his property. Law then was what it is now, and as Apothagos secured good lawyers to plead his case, on one technicality or another the matter was kept in litigation for years, meantime the structure continuing an eyesore to the Emperor and court. The matter was finally decided by the courts ten years after litigation had begun, and Apothagos was ordered to remove his wooden structure. But in the interval the Emperor Leo II. died, and his successor, paying little attention to such matters, and the building law having been disregarded in many quarters, the wily Apothagos obeyed by tearing down the wooden storeys and putting a brick and stone superstructure in their stead.

The Emperor Zeno, directly after his accession in A.D. 474, undertook to reform the Constantinople buildings, and promulgated a building edict limiting all future tenement structures to 100 feet in height, provided the street in front was 100 feet feet wide. Constantinople then suffered as much from fire as it has done under the rule of the Turks, and it was after one of these great periodic conflagrations that the reform of Zeno was begun. The burned district lay to the north of the peninsula, and Zeno's architects, following the example set by Nero, disregarded all former streets and boundaries, and laid out new avenues straight from the top of the hill to the water, crossed at right angles by streets running parallel with the shore. The streets from the hill to the water were 100 feet in width, while the avenues crossing them were 60 feet, and just in front of the imperial palace a grand avenue 150 feet in width, leading straight to the water from the central palace gate, was projected. This portion of Constantinople was thus made regular, and it is the only part of the city that now has wide streets and avenues crossing at right angles, for ere Zeno could carry out his plan for rebuilding the entire city he died, and the scheme was given up by his successors.

There is abundant evidence that high buildings, or at least buildings of a height that the ancients were not supposed capable of reaching, were to be found in almost every large city of antiquity. It is said by Herodotus that there were houses in Babylon of four storeys in height, while the Carthage houses often exceeded six storeys. The city of Tyre was limited to an island where the circumscribed area made property expensive, and consequently high houses were the rule at Tyre, as in Constantinople and Rome. Houses of ten storeys were mentioned by several Greek historians as being numerous in Tyre and other seaside cities of the East. We know that the tenement houses of Jerusalem must have been very high buildings, as eight and ten storeys are mentioned, and one rabbi speaks of having to climb over 100 feet in the air before he could reach his room. Athens had a building law limiting the height of structures for residence purposes to ten storeys, though the height of these storeys is not mentioned.

The walled cities of the Middle Ages rendered land valuable for building, and consequently, to secure proper returns, capitalists were forced to erect high structures. On the other hand, therefore, the legal authorities were obliged to enact binding laws to prevent these buildings being so lofty as to endanger the public safety. The islands on which Venice was built were limited in area, and property was very valuable, so much so, in fact, that the Council was compelled to pass a building law limiting the height of buildings to 70 feet. In Florence, so long as the city was confined by walls, the limit was 100 feet; in Paris 60, in Toledo 75 feet. Rheims had a curious building law, forbidding any structure for residence purposes to be erected higher than the eaves of the cathedral, and it is recorded that whenever a building was going up the sexton was enjoined to look out daily from the portholes in the eaves and see that the walls of no structure rose higher than the level of his eyes. The burghers of Amsterdam probably borrowed the idea from the Council of Rheims, and ordered that no tenement or residence house should be higher than the third storey of the Rathhaus, this building being the pride of the city, being thus jealously preserved in its pre-eminence over all others.

The building laws of both ancient, Mediæval and modern times have not generally applied to structures other than residences and office property, and it is marvellous to what an extent the architects of ancient and Mediæval days succeeded in rearing strong, stable and lofty buildings. The Birs Nimroud, or Tower of Babel, now only a mound, has been partially excavated, and from the portions that have been uncovered it is estimated that this tower or temple must have had sixty storeys and been from 500 to 800 feet in height. The Pyramids of Egypt, among the earliest human monuments, are also the most stupendous. The base of the Great Pyramid covers 13 acres of ground, and the height is slightly above 500 feet. In other words, the great pyramid of Cheops is almost exactly

the dimensions of Pilot Knob in the southern part of Missouri and this huge pile is of solid cut-stone throughout. Giant structures are not confined to Egypt or Europe, for the temples in India rival in extent and magnificence those of the most cultured nations of the West. Nor has even the Old World a monopoly of tall buildings, for the Mexican pyramids, erected at an unknown period, rival in size and dimensions the second-class pyramids of Egypt.

In comfort and convenience no dwellings of any age can compare with those of our own day, but so far as solidity of construction is concerned the ancients built as substantially as the moderns, and in even the great tenement buildings of Rome, Constantinople, Tyre and Jerusalem the quality of the materials employed and the close inspection of government officials rendered these structures so substantial that the falling of a house from any cause, save by fire, was a comparatively rare occurrence.

WATER-SUPPLY OF FLORENCE.

IN the year 1896 the total consumption of water in Florence amounted to 874,748,380 gallons. The total number of concessions granted for domestic use was 4,834. Nearly every house is provided with a well, of which about 13,000 exist in Florence. Well-water generally rises from a depth of 29½ to 36 feet from the surface of the soil, its temperature being from 57 degs. 2 mins. to 60 degs. 8 mins. Fahr. Of late years a few of these, being reputed unwholesome, were closed by the municipality. The quality of the public water is satisfactory under ordinary circumstances, but is said by hygienists to be liable to become contaminated and consequently a source of public infection. It is also held to be decidedly scarce in quantity greatly to the detriment of the public services, especially watering of the streets, boulevards, &c., this scarcity being also an obstacle to the general suppression of private wells which might eventually become a cause of infection.

A scheme to provide water from the Sieve was sanctioned by the Grand Ducal Government as early as 1857, but the commune was obliged to give it up on account of the great cost of the enterprise. In 1867 the municipality bought some springs at Rignalla with a view to bringing their water into the town, but even in this instance the project was abandoned on account of the scarcity of water available therefrom. Two years later a municipal commission appointed for the purpose fully reported on the matter, but nothing was done until 1870, when the Montereggi aqueduct was transferred to the commune and improved.

In 1872 the scheme for the present system (Anconella tunnel) was brought forward and met with the approval of the commune; the works were speedily commenced and completed in 1877, their rapid completion being due, as in the case of other great public works, to the energy and good offices of Commendatore Ubaldino Peruzzi, at that time Syndic of Florence. The supply so obtained was, however, not found in course of time very satisfactory either as to quality or quantity, and a competent commission appointed in 1886, after careful chemical and bacteriological analysis, reported it to be "fairly good but liable to contamination." The matter was therefore brought again into discussion and a new commission appointed.

The latter presented in 1893 an elaborated scheme for bringing the water from the "Garfagnana" by an aqueduct sixty-four miles in length at an expense of about 800,000*l.* The project was, however, objected to and abandoned. The commune decided, therefore, to entrust the study of the question and of further schemes to the permanent municipal commission of works, who having examined eight new projects, reported upon them on May 14, 1895. Of these, three only were found worthy of serious consideration.

1. Messrs. Luciani Brothers' project to obtain the water from the Monte Amiata by an aqueduct 72½ miles in length at an expense of 640,000*l.*, giving 5,280,000 gallons per diem (24 hours). The board rejected it on the ground that there was no guarantee that the water was good, and that the estimated cost was too much under the mark, calculating that it might exceed 920,000*l.*

2. Project of Engineer V. Bibolini—source, Pistoja Apennines; output, 6,600,000 gallons per diem (24 hours); cost, 320,000*l.* Objected to for technical reasons.

3. Messrs. Vestrini & Bibolini's project for an aqueduct to bring the water from the Gangheri and Chiesaccia (Garfagnana); length, 62 miles; output, 6,600,000 gallons; to be constructed at their risk for 440,000*l.* This was preferred to the others by the board, with some modifications. The board, however, advised the Giunta to have tenders for the grant of the concession on the main lines of the above project, but under conditions fixed by the commune and suggested by said board. This project was analogous as far as the source of supply is concerned to that proposed by the commission of 1893 and rejected by the commune.

A new proposal, which was said to be very advantageous for the commune, was at this time submitted by another company (Del Poggetto's project) on the lines of that suggested by Engineer V. Bibolini, for obtaining the water from the Pistoja Apennines. Obstacles, however, arose on account of the important mills existing in that district, especially at San Marcello, where hydraulic power is used up to 300 horse-power and which would have been deprived of the same, and above all on account of the practical difficulties to collect together the water of the numerous small springs in that district. For this and other reasons this project failed and gave way to that of Messrs. Boggio & De Niccolo, by whom at last a preliminary agreement was prepared and sanctioned both by the commune and prefecture on July 9, 1897.

The detailed technical project has not as yet been published nor the contract signed. It is, however, held in official quarters that the company, a solid and reliable one, will be but too ready to undertake the enterprise about which they have already incurred some expenses for preliminary studies, &c. The company will bind themselves to bring into Florence every twenty-four hours 6,600,000 gallons of drinking-water of excellent quality, to be derived either from the springs of the Pistoja Apennines or from the Turrita di Galliano (from the spring called "dei Gangheri") in the "Garfagnana," will provide the springs (except that of the Gangheri which already belongs to the commune), will make the necessary expropriations to construct the aqueduct and reservoirs, lay the mains, pipes, services, &c., all on account of the commune, which will immediately become proprietor of the plant. The company will have the right to exploit the aqueduct on their own account for fifty years.

The commune guarantees the sale of 1,100,000 gallons of water per diem after three years of exploitation and 1,320,000 gallons after five years. This guarantee will not be binding in case of wars fought in Italy, epidemics or other public calamities. It will completely cease when the sale of water for domestic use shall have reached 1,320,000 gallons per diem. The company will have to submit to the commune within a year from the date of the notification of the provisional concession from the superior authorities a complete plan of the plant. On receiving said concession, they will have to pay to the commune as a security 150*l.* of Five per Cent. Italian Rente.

Before the definitive project is approved, the water to be brought into the aqueduct will have to be carefully analysed by a special commission appointed by the commune in order to ascertain that the same is of the best quality and from natural springs. The supply may be effected in two distinct periods. In the first not less than 4,400,000 gallons per 24 hours will have to be provided within 30 months after the date of the definitive contract; in the subsequent period the supply will have to reach 6,600,000 gallons per 24 hours, as soon as the total consumption will be of 4,180,000 gallons per diem. In this case the works will have to be completed in eighteen months. Under any circumstances the same will have to be completed within thirty years from the date of the contract.

As an indemnity for all expenses incurred by the commune from January 1, 1897, up to the date of the execution of said contract, for laying new pipes and other unavoidable works to the mains, the company will have to pay a sum not exceeding 6,000*l.* The commune will grant the company during the concession the free use of the water of the spring of the Gangheri, that of the reservoirs of the Carraia, Pellegrino and Querce, and the whole plant underground. The company, with the consent of the commune, will, if necessary, modify this plant at their own expense.

Whenever required at the request of the committee, the company will construct at their own expense a reservoir of the minimum capacity of 880,000 gallons, near the one existing at the Querce, according to the exact plan approved by the commune. The commune will have the right of free use for all municipal requirements of 2,200,000 gallons of water per twenty-four hours. When the quantity of water sold for private use shall have reached 1,320,000 gallons per diem, the company will have a right to use within the communal territory, but outside the gates, and exclusively for the watering of the streets, squares and other public purposes, the water of the well of the Campo di Marte, which will be placed at the disposal of the company just as it is, together with the accessory buildings and machinery. In this case the company will construct at their expense the necessary conduits, reservoirs, &c., in such a way, however, as to be entirely separate and independent from the other system, and always subject to the approval of the communal council, and under the strict surveillance of the same. The company will be exempt from all direct communal taxes for the construction as well as for the exploitation of the aqueduct, and from octroi duty on the pipes, &c., but not from any other tax. The commune will be entitled to use the water obtained through special pipes laid at its expense from the tunnel of the Anconella or from any other old aqueduct or spring, excepting that of the Campo di Marte, for the purpose of cleansing public drains, watering streets, public gardens, &c., but in no case shall this water be

introduced in the mains and reservoirs used for drinking water. As soon as the consumption has reached 1,320,000 gallons per day, the company will be bound to pay the commune an annual sum of 324*l.* for every additional 44,000 gallons of water sold per diem.

The duration of the exploitation on the part of the company fixed at fifty years will commence from the day on which the distribution of the water into the town for public and private use actually takes place.

The aqueduct shall be constructed of metallic pipes of Italian manufacture. The project which has been at last selected appears to be very satisfactory in all respects. The water of the Garfagnana is of excellent quality from deep-lying springs. Moreover, the contract will finally insure a daily supply of 6,600,000 gallons (33 gallons per head), so that even calculating at 2,200,000 gallons per diem the water required for watering the streets and squares of the city (total area, 2,509,708 square yards), as well as for the fountains and other services, there will still remain an abundant quantity for domestic use (22 gallons per head per diem). The city will thus enjoy a larger water supply than the cities of Bradford (24 gallons), Nottingham (18⅓ gallons), Manchester (21 gallons), Burton-on-Trent (9⅛ gallons), Leeds (24 gallons), Birmingham (21 gallons), Liverpool (22⅕ gallons), and not much inferior to Edinburgh (39 gallons), and Dublin (36⅓ gallons).

The cost of the aqueduct is calculated at 440,000*l.*

INDIAN AND CHINESE INDUSTRIES.

A PAPER by Mr. W. C. Wood, M.I.M.E., late examiner to the Victoria Technical Institute, Bombay, published in the *Journal of the Society of Arts*, describes the "Effect of the Cotton Spinning Industry in China upon the kindred Industry in India." But the manner of conducting business in India and China is similar in all departments of industry. The following extracts from Mr. Wood's paper will have interest in other towns besides those of Lancashire :—

During the last ten years the cotton industry in Bombay has progressed by leaps and bounds. To an outsider it would indeed appear as if the trade were in a most prosperous condition. On giving the matter a moment's reflection, however, one is tempted to ask oneself this question, Are these new mills the result of *bona fide* prosperity in trade, or are they floated as pure speculations?

Now in India there is a very peculiar way of doing business. Suppose, for instance, three or four persons possessing a few thousand pounds between them desire to float a cotton-spinning concern, what do they do? Well, they get together a board of directors, register the company, elect themselves as agents or managing directors. In their articles of association they take very great care to insert a clause empowering them to charge a quarter of an anna commission on every pound of yarn spun or of cloth manufactured. This commission is paid to them whether the mill works at a profit or a loss.

Then, again, it often happens that the directors and agents are unable to raise sufficient capital to pay for the buildings and machinery and to work the concerns. In this case debenture shares are created, and loans are raised at a high rate of interest, with the result that what profit the mill had made goes to the agents in shape of commissions and in interest to loan capital. The writer calls to mind a case in which one lac of rupees annually was swallowed up in this manner, whilst the poor shareholders got nothing.

In addition to the agents making princely incomes from these concerns, many of their relations or friends manage to come in for some remarkably good pickings. It is really surprising what a number of separate and distinct businesses can be created, hanging on to and living upon the mills. You have, for instance, the cotton selector, the cotton broker, the muccadum or man who carts the cotton from the market to the mill, a man who makes a very respectable fortune in a very few years. Then there is the coal broker, the coal watcher, the coal muccadum—in fact, where a department can be created it is, and the happy possessor of that plum soon becomes rich and happy.

As to the mills and machinery, they are fitted with the latest improvements in engines, boilers and machinery in general. No expense is spared to equip them with the most modern appliances. They can fully bear the closest comparison with the most up-to-date concerns at home. The workpeople are skilled and attentive, and use the machinery well. In most concerns there is a European manager, who acts as a sort of supervisor. It is a surprising fact that although the natives have been familiar, and have become expert, in the use of cotton spinning machinery for over thirty years, they have practically done nothing themselves in making improvements. They accept and appreciate new ideas as they are brought out, yet they seem incapable of originating anything themselves—an Oriental trait. They are wonderful copyists, but poor originators.

The oldest cotton spinning mill in China has not been erected more than about nine years. It is true that a large mill was erected by Li Hung Chang, in Shanghai, a few years before then, but this mill was unfortunately burned.

Since 1891 great progress has been made. In Shanghai alone there are no less than eleven cotton mills. In the first six months of 1897 five new concerns commenced working, whilst up country several mills are already working, and there are numerous inquiries from projected new companies. So that it seems as if this industry had now established itself on a firm basis.

Naturally the first concerns were founded and worked by Chinese, with European supervision over the machinery. They themselves superintended the commercial department, so far with anything but satisfactory results.

In his own opinion, John Chinaman is a wonderful man, even if he does most things in exactly the opposite way to what he should. He has neither the faintest idea of taking stock nor of balancing his books at the end of the year as he ought to do.

The Chinese have only one holiday in the year, and that is at their new year, which date is movable, but generally falls some time in February. This is the time they square up everything and pay off all their debts. Anyone not being able to pay all his accounts and to start the new year with a clean sheet is posted as a defaulter, and is looked upon with suspicion by everyone. It is considered a family disgrace not to pay everyone up at that time. Naturally the people are preparing some weeks beforehand to arrange their business, so that they can clear off all outstanding accounts and be in a position to start *de novo*. From what one can see, this is the time John can tell whether he has made a profit or a loss in his business during the past year. He pays all his debts, and then sees how much money he has left, and so estimates his gains or losses. As we before remarked, the cotton spinning industry has not turned out a very profitable speculation when under exclusive Chinese management. The fact is, John tried to run before he had learned to walk. He was certain he knew how to manage a large concern, though he had had no previous training, and, in fact, knew far better than the Europeans he had specially engaged to teach him. The only natural results followed : he lost money and gained sense, with the result that most of the mills owned by Chinese in Shanghai either have been, or are, now in process of being transferred to European companies, to be worked and managed on exclusive European lines. One thing John intensely dislikes, and indeed seems utterly unable to do—that is, to look after "little things." He has only one spot where he can be touched, and that is—his pocket. He has a decided objection to spend money, and an all-consuming desire to make it. In furtherance of this weakness, he makes up his mind he will not pay high wages—and he does not. He engages numbers of what we should call "look-see" men, that is, gentlemen who are employed in walking round the mills to "look-see" if others are attending to their work. From a close and careful observation of these men, their commercial value would not be one dollar per dozen. "Eyes they have, but see not ; ears they have, but hear not." The wages of these gentlemen vary from 20 dols. per month down to 6 dols. Average them at 10 dols. ; the value of the dollar to-day is 2*s.*, which gives them some 5*s.* per week of wages. It must be borne in mind that they are married men, and have to support families on this small sum. When one looks at the gorgeous silks and satins in which they are arrayed, one is tempted to ask one's self, How do they manage to dress and live on such pay? To an outsider this would be a subject for anxious inquiry, but to one who knows the answer is given in one word, "Squeeze," with a big capital "S."

Yes. Squeeze is the beginning and the ending of all business in China. It is the life thought of the proprietor's servant, who receives some 6 dollars a month as pay, and who somehow or other manages to keep a wife and family in good condition, can dress in "crushed strawberry" silk breeches, and a gorgeous lavender-coloured satin coat. You may rack your brains in trying to elucidate the problem as to how it is done and find no answer. Perhaps, however, during the process of investigation you may want to see his master on business. He cannot be approached, for he is a mandarin of sorts, without being announced by his servant. Having sent in your card with a request that you wish to see him on a matter of important business, the servant returns and says he is very sorry, his master is asleep and cannot be awakened, or he is sick and cannot be seen. You return next day, when the same or other plausible answer is given, and so on till you wake up to the truth and pay. Then you can understand the silks and satins and other trifles, which were a mystery before.

And so it is in all grades, from the highest to the lowest, and from the richest to the poorest the great problem is, How can we get a squeeze? Everything has to be paid for. It is a game of chance ; you approach the official, whoever he may be, and intimate to him you are wishful for service, and what you are prepared to pay. It is a case of cash down; you have

to part there and then, and on the strength of this "comshaw," or squeeze, he approaches the principal and represents your case to him. If he is eloquent, or has sufficient influence with his master, you obtain employment; if, on the other hand, he fails you have paid your squeeze and lost. You have had your chance and missed. One thing, however, remains—the squeeze is never returned.

Not only upon men is there a squeeze, but upon everything that is bought. Only the other day, having occasion to check eight large rolls of leather belting which had been purchased from a Chinese store, each roll was found to be 40 feet short in length—in all 320 feet. On referring to the storekeeper's books everything was found to have been checked and entered as correct. But where were the 320 feet? There is only one answer—they had gone in squeeze.

The first thing which would strike an outsider on walking through one of the mills under Chinese management is the excessive dirtiness around him. It is a fact that a Chinaman cannot see dirt. He will actually fall down through slipping on a dirty, greasy floor, and next day repeat the process, without it ever striking him to remove the cause. They are dirty, filthy, alike from the highest to the lowest. Dirt and disorder is the last thing they can or will see. Their houses are never cleaned, they have no comforts, and not many wants.

That nation which has the most wants or desires is the most civilised. China has very few. Her great desire is to be left alone in her dirt and squalor, and to be allowed to go on as she has gone on for centuries past. She cannot bear the poking up she is now receiving at the hand of the foreigners. When, however, John has been thoroughly aroused and brought into line he is anything but a fool.

In making a comparison between the workpeople, a wonderful difference is at once noticed between the Hindoos and Chinese. The customs, habits and manner of living at once declare themselves in the different races. Naturally India to-day has by far the most skilled workers, but I am most decidedly of opinion that in a few years' time the Chinese will be equal to them in every respect. The present state of efficiency in the operations at home was not arrived at in a day or even a year. They owe their foremost position as expert workmen to being trained from early childhood. China, in this respect, will be placed at a greater advantage than India, because the Hindoos only come to Bombay for a time, and then return to their native country to retire upon the money they may have saved. On the other hand, Chinese labour is recruited from the immediate districts in which the mills have been erected. The result of this is that several members of the same family find employment in the same concern as at home.

So great has been the demand for labour of late through such a number of new concerns having been started, that fully grown and old people have been engaged. Naturally, these people are too old to become expert and quick, and fail to give proper results. It is to the children who are now learning their business we have to look; and we may say that the greatest and most important work those Europeans have who are in charge of the mills in China is to break in this raw material, and to reduce it from its original condition of dirt and disorder to system and order.

Then, again, there is no Factory Act in China, nor any factory inspection to put a limit to the number of hours the people work, or to the age at which they commence to work. The writer has known many cases where children of not more than ten years of age have worked sixteen hours at one spell, with not more than two stoppages of fifteen minutes each during that time. In some of the mills the engines work 22½ hours out of the 24. Work is carried on night and day, with two shifts of hands. Those on day duty begin at 6.30 in the morning and work till 6 P.M. On Sunday, those hands who have worked all Saturday night have to clean the machinery, which takes till 10 or 11 o'clock, so that they have a long spell of work of something like 16 hours.

With regard to the raw material, the cotton, the condition in which it is bought and delivered to the mills is very different in each country. In India you can go to the cotton market, select your purchase, and have it delivered to the mills in a condition freed from seed and leaf, and pressed in bales, just as you can do in Liverpool. In China there are no presses worth speaking of. You can buy cotton in Shanghai which has been ginned at some of the mills (that is, it has been freed from seed and leaf), but the greater proportion comes down from the grower up country in bags made of rushes, exactly in the state it has been plucked from the plants. Many of the mills employ agents to buy direct from the farmers, who ship it to Shanghai in boats *via* the canals, creeks and rivers, which are the great means of communication.

A few remarks on the cultivation of Indian cotton may not be uninteresting. It is a fact that Indian grown cotton does not improve in quality, in cleanliness, and in staple, or in yield per acre, as one would naturally expect. There does not appear to be any attempt made to improve its cultivation by selecting the best seeds or by fertilising the land. Why? The answer is very short and very simple. The land belongs to the ryots, and has most likely been in their families for generations. Now, everyone knows that the poor ryot is a man who cannot make both ends meet, and mortgages his crops long before they are ripe. In case of sickness or of famine, or when there is a wedding in his family, he needs ready cash, and consequently goes to the marwarri, or moneylender, who kindly obliges him, and soon loads the original amount with interest and compound interest to such an extent that the poor ryot can never get free from him. Nominally the owner of the land, he is in reality nothing more than the servant of the moneylender. He lives from day to day—a never-ending round of toil; his hours of work are from sunrise to sunset; he has no aspirations, nor any desire to free himself and to get on; he is just as his father was, and his children will have no other ambition than to be just as he is. And thus it is, year in and year out, the same round of toil and of labour and of hopeless debt ever hangs over him, and a life is lived with no incentive to better himself by improving either the quality or the yield of his crops.

The ground is tilled with the same rude, wooden ploughs, shod with a tip of iron; and the seed is taken from the previous year's cotton, whether it was of good or of bad quality matters not, in exactly the same way it was centuries ago.

In China you can depend upon getting the pure and unadulterated article you purchase, because it undergoes all its processes under your own observation. On the other hand, in India the natives are rather more astute. They have arrived at the knowledge of the truth that it is easier and more profitable to grow sand than cotton, and if they can mix a poor with a better grade along with a sprinkling of sand, why a good day's work has been done. As regards the future outlook of this new industry in China and the effect of its competing with India, the case appears almost parallel to that of Lancashire and Bombay some years ago. Lancashire lost her trade in low numbers in the East for the simple reason that she could not compete with Bombay with its cotton grown on the spot and its cheap labour. It seems very probable that Bombay will just take the place Lancashire did, and she will have to do what her old rival did—she will have to find new markets. With a population of over 280,000,000 at her doors it does not seem unreasonable to think that she could easily find an outlet for her manufactures in supplying yarn for the clothing of her teeming millions.

Ought we not to look upon this development with feelings of pleasure, and not with feelings of antagonism? For is not each new mill or manufactory which is erected a great civiliser and a great teacher, and will not these new industries play a very important part in the awakening of China? A remark made to me by a mandarin, as he was inspecting a large cotton mill, shows that these industrial concerns do arouse within them feelings of sorrow for their country. "Ah," said he in a tone of sadness, "this is the work of foreigners; we could not do these things." If high officials begin to think thus, and can see how backward they are among nations, it is certain then that every new mill erected will play some part in helping on the time when China shall become awakened from the great sleep which has overcome her.

PUEBLO MASONRY.*

THE ancient pueblo builder, like his modern successor, was so closely in touch with nature, so dependent on his immediate physical surroundings, that variations in some at least of his arts are more natural and to be expected than uniformity. Especially is this true of the art of construction, and variations in masonry are more often than not the result of variations in the material employed, which is nearly always that most convenient to hand. Yet there were other conditions that necessarily influenced it, such, for example, as the character of the structure to be erected, whether permanent or temporary.

The highest type of masonry in the pueblo system of architecture consists of small blocks of stone of nearly uniform size, dressed and laid in courses, and rubbed down *in situ*. No attempt was made to break joints. This system requires the careful preparation of the material beforehand. As a variant we have walls composed of stones of fairly uniform size, laid with the best face out and with the interstices chinked with small spalls. Chinking is carried to such an extent in some places that the walls present the effect of a mosaic composed of small spalls. Chinking is almost a universal practice, and in some localities had passed, or was passing, from a mere constructive to a real decorative feature. Here we have the beginning of that architecture which has been defined by Fergusson as "ornamental and ornamented construction"—in other words, of architecture as an art rather than as a craft.

* A paper by Mr. Cosmos Mindeleff in the sixteenth annual report of the Bureau of American Ethnology.

The use of an exterior finish of plaster was conducive to poor masonry. Such plastering is found throughout the region, but it is much more abundant in the modern than in the ancient work. Perhaps we may find in this a suggestion of relative age, not in the use of plastering, but in its prevalence.

Pueblo masonry is composed of very small units, and the results obtained testify to the patience and industry of the builders rather than to their knowledge and skill. In fact, their knowledge of construction was far more limited than would at first sight be supposed. The marked tabular character of the stone used rendered but a small amount of preparation necessary for even the best masonry. For over 90 per cent. of it there was no preparation other than the selection of material. The walls and buildings were always modified to suit the ground, never the reverse, and instances in which the site was prepared are very rare, if not indeed unknown.

Chinking was sometimes done, not with slips of stone driven in with a hammer, after the usual style, but with bits of mud pressed in with the fingers. The mud was used when about the consistency of modelling clay, and bears the imprints of the fingers that applied it; even the skin markings show clearly and distinctly. From this use of mud to its use as an exterior plaster there is but a short step. In plastered walls the process was carried a step further, and the surface was finished by the application of a final coat of mud made quite liquid. The interior plastering of kivas was always much more carefully done than that of any other walls. Owing to blackening by smoke and recoating, the thickness of the plastering in kivas can easily be made out. Often it is as thin as ordinary paper.

It seems probable that the application of plaster as a finish grew out of the use of stone spalls for chinking, and its prevalence in modern as compared with old structures is suggestive. Surface-finishing in mud plaster is the prevailing method at the present day, and well-executed masonry of stone carefully chinked is almost invariably ancient. The use of surface-plaster is largely responsible for the deterioration of stonework that has taken place since the beginning of the historic period. The modern village of Zuñi, which dates from the beginning of the eighteenth century, although built on the site of an older village, is essentially a stone-built village, though that fact would never appear from a cursory examination, so completely is the stonework covered by surface plaster.

In Tusayan (Moki) walls have been observed in progress of erection. The stones were laid up dry, and some time after, when the rains came and pools of water stood here and there in pockets on the mesa top, mud mortar was mixed and the interstices were filled. This method saved the transportation of water from the wells below up to the top of the mesa, a task entailing much labour.

It is probable that the practice of chinking grew up out of the scarcity of water, when walls were erected during the dry season and finished when the rains made the manufacture of mud mortar less of a task. Chinking, both with mud and with spalls, was extensively practised.

Although walls were often built on sloping rock, and the builders had experience, and at times disastrous experience, to guide them, the necessity for a flat and solid foundation was never appreciated. Walls were sometimes built on loose *débris*; even refuse which had been covered and formed an artificial soil was considered sufficient.

It is well known that sheep were introduced into this country by the Spaniards, and the presence in the ruins of sheep dung, or of a material closely resembling it, is important. Much of this is due to subsequent Navaho occupancy, and many ruins are used to-day by these Indians as sheepfolds. It is said, moreover, that at the time of the Navaho war, when the soldiers bayoneted all the sheep they could find, large flocks were driven up into some cliff ruins that are almost inaccessible and kept there for a time in security. But many instances are found where the walls rest directly upon layers of compacted dung.

It has been suggested that the compacted dung found in the ruins was the product not of sheep, but of some other domesticated animal which existed in this country at the time of the first Spanish invasion, but the evidence to support this hypothesis is so very slight that so far the suggestion is only a suggestion. Not the slightest trace of this animal has been found, although it is alleged that it was domesticated among the pueblos 350 years ago.

Although the idea of a strengthening or supporting buttress is thought to be a foreign introduction, a hypothesis that is strengthened by the occurrence of other features, the masonry is aboriginal in its principles, and probably also in execution. The conservatism of the Indian mind in such matters is well known. The Zuñi to-day use stone more than adobe, although for a hundred years or more there has been an adobe church in the midst of the village.

Adobe construction in this region is only partially successful. North of the Gila river, in the plateau country, the climate is not suited to it; the rains are too heavy, and the frosts are destructive. Constant vigilance and prompt repairs are necessary, and even then the adobe work is not satisfactory. Certainly in the northern part of the country the aborigines would not have developed this method of construction in the face of the difficulties with which it is surrounded. The fact that the only previously known examples of adobe work occur in ruins which are known to have been inhabited subsequent to the Spanish conquest, such as the ruin of Awatobi, in Tusayan, is suggestive. Moreover, adobe construction in this region belongs to a late period, for the walls are almost always very thin, usually 6 or 7 inches. The old type of massive walls, 2 or even 3 feet thick, are seldom or never found constructed of adobe, although such thickness is more necessary in this material than in stone.

There is another method of construction which, although not masonry, should be noticed here. This is the equivalent of the Mexican "jacal" construction, and consists of series of poles or logs planted vertically in the ground, close to each other, and plastered with mud either outside or on both sides Dr. W. R. Birdsall mentions walls in the Mesa Verde ruins which are "continued upward upon a few tiers of stone by wickerwork heavily plastered inside and outside," and Nordenskiold mentions a similar construction in the interior of a kiva

ROMAN VILLAS.

THE villa or country house of the Roman gentleman, properly so called, was often built near the sea, because, says Winckelmann, fevers or great heat were not experienced on the coast. The country house discovered at Herculaneum was situated on the edge of the sea, and a long causeway led from the garden to a circular summer-house, pierced with windows in every direction and situated in the sea itself. In short, the grand distinction from town houses consisted in the villas being insulated by a moat, single or double, with a wall between the two, or in their enclosing a piece of water. This last, like our modern public gardens, was surrounded with a piazza, divided by columns into boxes for conversation or bathing. Between the columns were placed busts and statues alternately. In general these houses had only one storey.

The country houses of Rome (properly defining the term) were villas of enormous magnificence and exquisite situation, but as the great public men could not be long absent from Rome, they had inferior and smaller residences in the outskirts of the city, which they called their gardens, and also villæ suburbanæ or suburbana. Of course those at Pompeii, being existing specimens, are the fittest to be considered.

These villas present nothing to the road but bare walls. The windows are all towards the garden like the houses of the East. In the centre of a square was a bath and ædiculum, the square formed by a piazza, the roof of which was a terrace, and at each of the hither corners at least was a summer-house. The plans were by no means uniform, and according to the Pompeian villas there is no important difference from the town house, except in the annexation of the garden, enclosed within a porticus or piazza.

The villa on the road, called of Herculaneum, was placed upon the edge of the declivity, which sloped towards the sea, and consisted partly of two storeys, the upper one being on the level of the street. It was spacious, and near the entrance was a bath, with all the necessary appendages. In the rear, the best rooms opened upon a terrace running the whole width of the house, and overlooking a garden or xystus, about 30 yards square. Under the terrace was a portico for exercise in shade or during rainy weather. At the further extremity a small temple, supported by six columns, projected towards the villa, and in its front a bath or basin occupied nearly the centre of the garden. The lower apartments, under the arcade, were paved with mosaic, coved and beautifully painted, as was also the greater part of the villa. One of the rooms had a large glazed bow window. The glass was very thick, and deeply tinged with green. It was set in lead, like a modern casement. In the cellars were many large earthen wine vases ranged in order against the walls. In that part of the lower storey which was removed from the covered portico the rooms, more simply finished, contained implements of husbandry. To this division of the house was a separate entrance.

The Roman villa was divided into three parts; the urbana, for the master and family, the rustica for the farmer and husbandmen, and the fructuaria, or storehouse for corn, wine and oil. The servants who were immediately attendant upon the master, and belonged to the villa urbana, were the atrienses, or what the Italians style the sala, in speaking of the livery servants collectively; the valets, cubicularii, who, it is presumed, were usually freedmen; the secretary, styled notarius; the gardeners for the pleasure garden, topiarii, and the musicians and comedians and persons for entertainment during repasts. This villa urbana, also denominated pseudo urbana, and prætorium from obvious distinction, had a peristyle or court, surrounded by a portico, at the further extremity of

which, opposite to the gate of entrance, was the atrium or hall, with a portico on each side, looking towards the place of exercise, as lawns, galleries for wrestling and other smaller buildings. The baths were also annexed to this part of the building, and were always so situated as to enjoy the winter's setting sun. Besides the sitting-rooms, chambers, library and dining-room—they would often have one of the latter kind, in the midst of the park, as we should call it—and sometimes a bedroom for the sake of quiet and retirement.

In the villa rustica or farmhouse, in apartments over the gateway, lived the procurator or steward, that he might know who went in or out; on one side of this, the villicus, bailiff or chief of the husbandmen, and near the fructuaria or storerooms, the villica or housekeeper, under whose order were the female servants employed in providing food and clothing for the family. The inferior slaves lodged in one great room, and the sick in an apartment called the valetudinarium. The lodgings of the freedmen had a southern aspect. The aviarius had the care of the poultry, and in considerable villas, far from a town, was a master of the workmen, ergastularius, with smiths and carpenters under him. Horses and mules were kept for the use of the master, and asses and oxen for that of the farm, which had yards much resembling the modern. Particular care was taken of the geese, hens, pigeons, peacocks and other birds, who had also separate dwellings assigned to them; and not only deer, hares and every kind of game was attended to, but there can scarcely be named an animal which was not kept by the more opulent Romans at their country seats.

The villa urbana or pseudo-urbana was also divided into a winter and summer house, because it had a suite of rooms adapted to either season. The parts which composed the summer residence were nearly the same as those of the town, except that the dwelling apartments, which did not commonly exceed one storey, were always surmounted by a tower, on the top of which was a room pierced with windows on every side, uniformly destined for meals, so that they could add to the pleasures of the table those of light and prospect. They nearly always built their villas along the high roads, for two reasons, one to get to them more easily, the other to place them more in sight. In the Pompeian paintings we have villas of this kind. One on the sea-shore, of two storeys, has trees planted on the roof. Winckelmann says that the architecture of the villas of Herculaneum is the same as that of the large houses of towns, so that the plan and elevation of the one is the same as that of the other.

TESSERÆ.

The Senses and the Arts.

OF the five senses which have been given to man, three—the taste, the smell and the touch—are incapable of awakening in us the sentiment of beauty. Joined to the other two they may contribute to extend this sentiment, but alone and by themselves they cannot produce it. Taste judges of the agreeable and not of the beautiful. No sense is so little allied to the soul and so much at the service of the body; it flatters and serves the grossest of all masters—the stomach. If the smell seems sometimes to participate in the sentiment of beauty, it is because the odour is exhaled from an object which is already beautiful in itself and beautiful in another way. Thus the rose is beautiful by its graceful outlines, and by the varied brilliancy of its colours; its odour is agreeable, it is not beautiful. Finally, it is not the touch alone which judges of the regularity of forms; it is the touch enlightened by the sight. There remains, therefore, only two senses to which all the world agrees in according the privilege of exciting in us the idea and sentiment of the beautiful. They seem more particularly at the service of the soul. The sensations which they give are purer, more intellectual. They are less indispensable to the mere physical preservation of the individual. They contribute to the embellishment rather than to the sustenance of life. They procure us pleasures in which we seem to have less a personal interest and more often forget ourselves. It is, therefore, to the sight and to the hearing that art must address itself, and address itself in order to penetrate to the soul. Hence the division of the arts into two great classes—arts of hearing and arts of vision. On the one hand, music and poetry; on the other, painting, with engraving, sculpture, architecture, and landscape gardening.

Vanbrugh and Blenheim.

In 1706 Parliament resolved to raise a public monument of glory and gratitude to the illustrious John Duke of Marlborough. They voted a splendid mansion without assigning funds to pay for it, but Queen Anne commanded the work to proceed, issued the money necessary for commencing it, and in compliance with the wishes of the Queen, of Sarah the Duchess, and the hero himself, Vanbrugh was named for architect. The design was made, the site, near Fair Rosamond's Well in Woodstock Park, selected, the foundations sunk and the first stone laid. Marlborough, after a series of splendid victories, when within one stride of France with his conquering army, was removed from his command and recalled, that in the insults of the court and the hisses of the people the world might see that England could be as ungrateful as any other country to the man who had saved her from destruction. Churchill was too proud to take much pleasure in a work voted for him by those who wronged him more now than they had honoured him before, and, moreover, he was too sensible of the value of money not to feel that as the Parliament had provided no fund for defraying the expense, any interference on his part might make him liable for the whole. These were no idle fears. During the life of Queen Anne the towers of Blenheim continued to rise; the workmen, though not regularly paid, seldom clamoured, as they believed the money to be safe; and the Duke himself, though he refused to give any directions, did not hesitate sometimes to pacify the masons and carpenters by paying their wages; believing, no doubt, that the Treasury would ultimately make good his advances. But Queen Anne died, the Treasury closed its doors, the Parliament eluded to fulfil their engagement, and the new king sat quietly down on his throne and allowed the hero, who had helped to establish it, to mourn his unfinished house and his ungrateful country. It will scarcely be credited, yet no fact is better established, than that the English Parliament ordered Blenheim to be erected—Queen Anne paid for what was built while she lived—the Duke paid a part—and Vanbrugh and his workmen did the rest at their own proper cost and charges. The situation of the architect was extremely embarrassing on the death of the Queen. He never had been rich and had laid out all the money he was master of on Blenheim. It would appear that he had obtained a warrant from Lord Godolphin giving him the power of making contracts on the part of the Duke of Marlborough, but the decision of the House of Commons that the mansion which they had voted was to be paid for by the Queen completely quashed this warrant, which Marlborough, moreover, refused to acknowledge, asserting that Godolphin was never empowered to act in his behalf, and that Blenhim was to be built for him and not by him. These difficulties, brought upon them by the shabby conduct of the Parliament, bred disunion between the architect and the termagant Sarah, and this soon extended to the Duke. A violent quarrel ensued. Vanbrugh declared that though he had always looked upon the Crown as engaged for the expense, the poor workmen considered the Duke of Marlborough as their paymaster, and that several contracts which he had made with them were with the concurrence of his Grace. Marlborough admits that he had occasionally advanced money to the men and that he had been cognisant of some of these contracts, but adds that he never for a moment conceived that the workmen were employed on his account. "If at last," says one who drew up the Duke's statement of the case, "the charge run into by order of the Crown must be upon the Duke, yet the infamy of it must be upon another, who was, perhaps, the only architect in the world capable of building such a house, and the only friend in the world capable of contriving to lay the debt upon one to whom he was so highly obliged." That Vanbrugh rated those high obligations very low may be gathered from the letters which he wrote at that period. In his view, if we may trust his language thoughout, he had done his duty and asked only what he was entitled to.

Selection of Subjects in Painting.

It is a matter of great judgment to know what subjects are or are not fit for painting. It is true that they ought to be such as are often prescribed, full of grace and majesty; but it is not every such subject that will answer to the painter. The painter's theme is generally supplied by the poet or historian; but as the painter speaks to the eye, a story in which fine feeling and curious sentiment is predominant, rather than palpable situation, gross interest and distinct passion, is not suited to his purpose. It should be likewise a story generally known; for the painter, representing one point of time only, cannot inform the spectator what preceded the event, however necessary in order to judge of the propriety and truth of the expression and character of the actors. It may be remarked that action is the principal requisite in a subject for history-painting, and that there are many subjects which, though very interesting to the reader, would make no figure in representation. Such are those subjects which consist in any long series of action, the parts of which have very much dependency each on the other, or where any remarkable point or turn of verbal expression makes a part of the excellence of the story, or where it has its effect from allusion to circumstances not actually present. For instance, a subject which was recommended to a painter by a very distinguished person, but who, as it appears, was but little conversant with the art; it was what passed between James II. and the old Earl of Bedford in the Council which was held just before the Revolution. This is a very striking piece of history, but so far from being a proper subject, that it unluckily possesses no one requisite

necessary for a picture; it has a retrospect to other circumstances of history of a very complicated nature; it marks no general or intelligible action or passion; and it is necessarily deficient in that variety of heads, forms, ages, sexes and draperies which sometimes by good management supply, by picturesque effect, the want of real interest in a history.

The Antique Tripod.

To the poet and the artist, the most interesting recollections and associations connected with tripods arise from the circumstances peculiar to the establishment of the oracle of Delphi. The first discovery of this oracle is said to have been occasioned by some goats which were feeding on Mount Parnassus, near a deep and large cavern with a narrow mouth. The goats were observed by a goatherd, called by Plutarch Coretas, to frisk and leap strangely, and to utter unusual sounds on approaching this cavern, upon which he had the curiosity to examine it, and found himself seized with the like fit of madness, skipping, dancing and foretelling things to come. At the news of this discovery multitudes flocked thither, and the surprising place was soon covered with a kind of roof originally made of laurel boughs, but finally converted into a temple. Such indeed was its reputation, and such the multitudes who came from all parts to consult the oracle, that the riches brought into the temple and city became comparable to those of the Persian kings. At first, the whole mystery requisite for obtaining the prophetic gift was to approach the cavern and inhale the vapour issuing therefrom; but at length several enthusiasts, in the excess of their frenzy, having cast themselves headlong into the chasm, it was thought expedient, by way of prevention, to place over the hole whence the vapour issued a machine which they called a "tripod," because it had three feet. Upon this chair a woman was seated, imbibing the vapour without danger, the three feet of the machine standing firmly on the rock. This priestess was named Pythia, the Greek etymology of which word is "to inquire." The oracle could only be consulted on certain days, and, excepting on these, the priestess was forbidden, under pain of death, to go into the sanctuary to consult Apollo. Alexander, before his expedition into Asia, came to Delphi on one of the forbidden days, and entreated Pythia to mount the tripod, which she steadily refused. The impetuous prince, not brooking opposition, drew her by force from her cell, and on their way to the temple she took occasion to exclaim, "My son, thou art invincible." As soon as these words were pronounced, Alexander cried out that he was satisfied, and would have no other oracle. Strange and ghastly contortions were said to have agitated the priestesses on ascending the tripod. They attempted to escape from the priests, who detained them by force. At length, yielding to the impulse of the god, they gave forth some unconnected words, which were put into wretched verse by the poets who attended, giving occasion to the raillery that Apollo, the prince of the muses, was the worst of poets. This oracle was, like all others, obscure and ambiguous, and its retailers not inaccessible to the temptations of corruption. Its priestesses were remarkable for the pallid horror of their visages, and the resistance made by them no doubt resulted from the anguish of convulsed and shattered nerves. Montfaucon has published several ancient tripods, among which we find one which was discovered in 1629, near Frejus, and which furnished to Peiresc the subject of his "Dissertation sur un Trépied ancien." The greater part of these tripods have a solid base; but two of them are disposed in such a manner as to be able to receive, at their upper part, a vase greater or less in diameter.

New Styles.

As regards the attempt to invent or introduce new styles, whether in architecture or in any of the arts, in painting, in sculpture, in poetry, in costume or in gardening, we must ever bear in mind that there are many persons, and those of great taste and extensive cultivation, who make a point of deciding on the beauty and real merit of every style, and indeed of every new production, not by its own intrinsic excellence and accordance with taste, but solely by its accordance with what has been produced before, and by its correspondence with already approved models. If it coincides with them, however indifferent it may be in itself, its excellence is undisputed and is deemed indisputable. If it varies from them, however beautiful or tasteful in its design, it is declared to be intolerable, because at variance with the orthodox standard. Such a mode of deciding upon the merit of an artistical performance is, of course, fatal to originality, and, if consistently carried out, to all advancement and improvement whatsoever. The only sound and correct mode of determining the claim of any new effort in all these cases must necessarily be by ascertaining whether it is in accordance with taste and with the real principles of art and nature, the sole criterion by which the merit of every work of art, of whatever kind and whatever period, must be decided. Nevertheless in the effort to invent new styles in architecture, or indeed in costume or any other art, the greatest care must be taken that our originality does not lead us into extravagance, and that deformity instead of beauty is not the result. In all these cases invention requires, not indeed to be checked, but to be controlled and kept in order by the reason. Invention equally with taste and imagination needs discipline and training and correction to prevent it from running wild, and from becoming barren and bearing no fruit, and the more vigorous and more extensive is the inventive power the more essentially does it stand in need of this supervision.

English Gardens.

It is stated by Fitzstephen that in the time of Henry II. the citizens of London had large and beautiful gardens attached to their villas. In the reign of Edward I. it may be collected from Hollinshed's "Chronicle" that the cultivation of the garden was extended to the more curious and delicate productions; but the wars of York and Lancaster destroyed all these occupations, and gardens in general ceased to be more than pleasure-grounds or kitchen-gardens of the rudest kind until the time of Queen Elizabeth. King James I. of Scotland describes the garden at Windsor Castle, where he was confined by Henry V., as a place set thick with trees and alleys of hawthorn, with an arbour in each corner. Much later, in the year 1512, the great Earl of Northumberland, whose household consisted of 160 persons, "had but one gardener, who attended hourly in the garden for setting of erbis, and clipping of knottes, and sweeping the said garden clean." In the gardens of Nonsuch, the palace of Henry VIII., constructed about the year 1540, we hear of shady walks, columns and pyramids of marble, "fountains that spout water one round the other like a pyramid, upon which are perched small birds that stream water out of their bills," and of similar objects, but nothing of the more essential part of a garden—its plants. Pleasure-grounds of this description, indeed, have existed in England ever since the Conquest.

GENERAL.

The Comte de Castellane has purchased the portrait of *Nicolaes Rueto* by Rembrandt, which is one of the most admired works of the master.

Bernini's Bust of Cromwell, which Mr. Charles Wertheimer has presented, is to be placed in the lower waiting-hall of the Houses of Parliament, in such a position that it will be visible to all approaching the Central Hall from St. Stephen's Porch.

M. Valabrègue, the French writer on art, has been sent to Germany by the Minister of Fine Arts in order to study the works by Chardin the painter and Houdon the sculptor, which are found in some of the museums in that country.

Messrs. Field & Co. have served a writ on the Brighton Town Council in connection with their claim for 3,215*l.* on account of the contract for erection of the technical school. The town clerk was at the last meeting instructed to defend the action.

Lord Leighton's House, in Kensington, is open to the public on the Wednesdays and Saturdays of the present month, from eleven until seven o'clock. No less than 500 pictures have recently been added to the collection upon the walls.

The Celtic Goldsmiths' Work lately acquired by the British Museum from the North of Ireland, and consisting of a torc, a boat, a cup and several chains, is likely to be transferred to the Museum of the Science and Art Department in Dublin.

A Statue of Prince Bismarck erected by voluntary subscriptions collected since his eightieth birthday, April 1, 1895, was unveiled at Altona on Saturday amid a scene of considerable enthusiasm. The venerable ex-Chancellor telegraphed to the burgomaster from Friedrichsruh to express his gratification and thanks.

Sir William Fraser, Deputy-Keeper of the Records of Scotland, who died on June 15 last, leaving personal estate worth 104,728*l.*, bequeathed 25,000*l.* for the foundation and endowment of homes for the poor in the city or county of Edinburgh, especially for authors and artists who may from no fault of their own have fallen into distress, and 25,000*l.* to found and endow in the University of Edinburgh a Professorship of Ancient History with special reference to the records and charters of royal, noble and baronial families, to be called "The Sir William Fraser Professorship," and 10,000*l.* for the library of the University, to be applied as to two-thirds of the income in increasing the salaries of the librarians and other officers, and he left the residue of his property to be applied for the general purposes of the University of Edinburgh and to the Royal Infirmary. Sir William Fraser also authorised the publication, at an expense not exceeding 3,000*l.*, of such documents as the trustees may think proper for illustrating the history of the antiquities of Scotland.

THE

Architect and Contract Reporter.

IMPORTANT NOTICE.

WORKMEN'S COMPENSATION ACT.

In view of the many difficulties which are certain to arise in connection with the law, practice rules and procedure under the above Act, we have added to our staff A VERY EMINENT BARRISTER, who has made the subject a special study, and will be glad to answer in the columns of this paper any questions relating to the complicated matters arising from the provisions of this difficult Act. Our LEGAL ADVISER will further answer any legal question that may be of interest to our readers. All letters must be addressed "LEGAL ADVISER," Office of "The Architect," 175 Strand, London, W.C.

EDITORIAL NOTICES.

The authors of signed articles and papers read in public must necessarily be held responsible for their contents.

No communication can be inserted unless authenticated by the name and address of the writer—not in every case for publication, but as a guarantee of good faith.

Correspondents are requested to make their communications as brief as possible. The space we can devote to Correspondence will not usually permit our inserting lengthy communications.

TENDERS, ETC.

*** *As great disappointment is frequently expressed at the non-appearance of Contracts Open, Tenders, &c., it is particularly requested that information of this description be forwarded to the Office, 175 Strand, London, W.C., not later than* 2 P.M. *on Thursdays.*

NEW READING CASE.

To Librarians of the Public Libraries and Reading-rooms.—A new handsome Reading Case can be supplied at a nominal charge of 2s., by post 2s. 6d., on early application to the Publisher, 175 Strand, W.C.

For Advertisement Scale, see page xiii.

* Accepted provisionally.

THE interesting old church of St. Mary of the Greeks, Hog Lane, Soho, is doomed. It was built in 1676 by Georgeirises, Archbishop of Samos, but was afterwards converted into a Huguenot chapel. Whilst it was thus occupied it was introduced by Hogarth in his famous picture *Noon*. This relic of Old London is now in course of demolition in order to make way for "modern improvements" sadly needed in its neighbourhood.

ELECTRIC NOTES.

ARRANGEMENTS are being made to drive the workshop machinery at Portsmouth dockyard by electricity. A generating station is to be built on the site of the old Portsea convict station, and the whole plant is estimated to cost half a million sterling.

THE results of the year's operations of the Edinburgh electric lighting from May 15, 1897, to May 15, 1898, have just been made up, and are eminently satisfactory. The total output has been :—For private lighting and power, 2,059,763 units —an increase over the previous year of nearly 90 per cent. The total units for public lighting has been 834,660, making a grand total of 2,894,423 Board of Trade units. The income from private lighting and power has been 30,024*l.* 4*s.* 2*d.*, and from public lighting 7,993*l.* 5*s.*, making in all 38,017*l.* 9*s.* 2*d.* The expenditure has been :—For generation of electricity, distribution, management, rates and taxes, upkeep of public lamps and all expenditure in connection with the undertaking, except interest and sinking fund, 16,744*l.* 15*s.* 4*d.* ; interest and sinking fund, 13,623*l.* 6*s.* 7*d.* ; making a total expenditure of 30,368*l.* 1*s.* 11*d.*, and leaving a net profit on the year's working of 7,649*l.* 7*s.* 3*d.* Of this sum, 4,000*l.* is to be put to reserve, leaving 3,649*l.* 7*s.* 3*d.* available as a contribution to the rates, or 1,649*l.* 7*s.* 3*d.* more than was estimated. This, however, is not all that the rates receive through the operations of the electric lighting, for the burgh assessments on the undertaking amount to 763*l.* 18*s.* 5*d.*, and the poor and school rates to 617*l.* 6*s.* 8*d.* Thus the rates benefit in all from the undertaking for the year just closed by no less a sum than 5,030*l.* 12*s.* 4*d.*, in addition to a charge of over 1,000*l.* for the town clerk, collector and Chamberlain's departments.

AT a meeting of the electricity committee of the Glasgow Corporation it was reported that the gross income, including receipts from private and public lighting for the year just ended, was 36,360*l.*, as compared with 30,474*l.*, being an increase of 5,886*l.* These results have been obtained notwithstanding the reduction made a year ago in the price of electricity, and after meeting the cost of production the balance is carried to depreciation and sinking funds. Owing to the expression of a good deal of dissatisfaction at the present method of charging, the committee is considering the advisableness of making a change.

CORRECTION.

WITH our last issue were given two illustrations which showed the effect of the faïence work in the new branch of the National Provincial Bank of England in Piccadilly. In connection with these illustrations we said that the work had been supplied by Mr. Alfred Whitehead, of Prudential Buildings, Leeds, which statement was an accidental and regrettable error. The work was supplied by the Campbell Tile Company, of Stoke-on-Trent, and very beautiful work it is. Our illustrations showed this very clearly, but they did not and could not show the delicately subdued colours of the work, and the artistic and harmonious manner in which they are blended.

The erroneous attribution of the work was quite unnecessary, for Mr. Whitehead's productions in faïence and ceramic decoration are well known for their excellence. Specimens thereof are to be seen in the Grand Arcade in the Briggate, Leeds; the Oldham Joint Stock Bank; the new theatre at Morecambe and other important buildings.

SCHOOL OF MEDICINE FOR WOMEN.

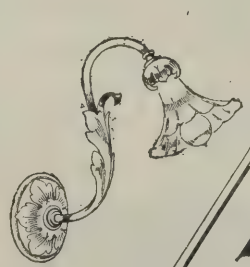
BLOOMSBURY brightened up considerably in honour of the visit on Monday afternoon of the Prince and Princess of Wales, who came to open the new science laboratories in connection with the School of Medicine for Women. This important school having quite outgrown its old quarters, further accommodation had to be found, and the Council having obtained a long lease of the old site from the governors of the Foundling Hospital are rebuilding on a much larger scale. The new building, which will be erected in three separate stages, will consist of three blocks, which will be known as the Wakefield or Pfeiffer wing, the Handel Street and the Hunter Street wings. The want of laboratories has long been felt, and in order to facilitate the operations of the school, the first-named block has been taken in hand, and was yesterday opened by the Princess of Wales. Built at a cost of between 9,000*l.* and 10,000*l.*, this wing provides adequate rooms for the teaching of chemistry, physiology, anatomy and physics. It has been paid for partly by donations, by a loan from the general funds and by a sum of 4,000*l.* bequeathed to the school by the late Mrs. Pfeiffer, whose name the new block will bear. The remaining building will involve a further expenditure of 15,000*l.* The estimated cost of the second wing, which will contain two lecture-rooms and a corridor with a north light for microscopic work, is 5,000*l.* The construction of the third wing will not be embarked upon until the second block has been paid for.

TRADE NOTES.

THE Plasnewydd school, Maesteg, is being warmed and ventilated by means of Shorland's patent Manchester grates.

A LARGE clock, with two dials, chiming the quarters and striking the hours, has just been erected in the church at Cheveley, near Newmarket, by John Smith & Sons, Midland Clock Works, Derby.

THE whole of the work in connection with the restoration of the Catholic church of St. John the Evangelist, Easingwold, Yorks, including new roof, new stone buttresses, new porch to west entrance, &c., has been entrusted to Mr. Anthony Lyons, builder and contractor, of Norton, Malton.



THE foundation-stone of a Roman Catholic church at Brockley was laid on the 9th inst. The new building will cost rather more than 3,000*l.*, and will have seating accommodation for 600 persons.

THE Rugby Portland Cement Company inform us that they have acquired the works hitherto belonging to the Rugby and Newbold Cement Company, and that, as from August 1, the business of that company will be amalgamated with theirs, and carried on by them under one management and under the style of the Rugby Portland Cement Company. They intend to make considerable additions and improvements to the works, and hope shortly to largely increase their output. The past history of the company may be regarded as a guar-

antee of an exceptionally successful future, for which it certainly has our best wishes.

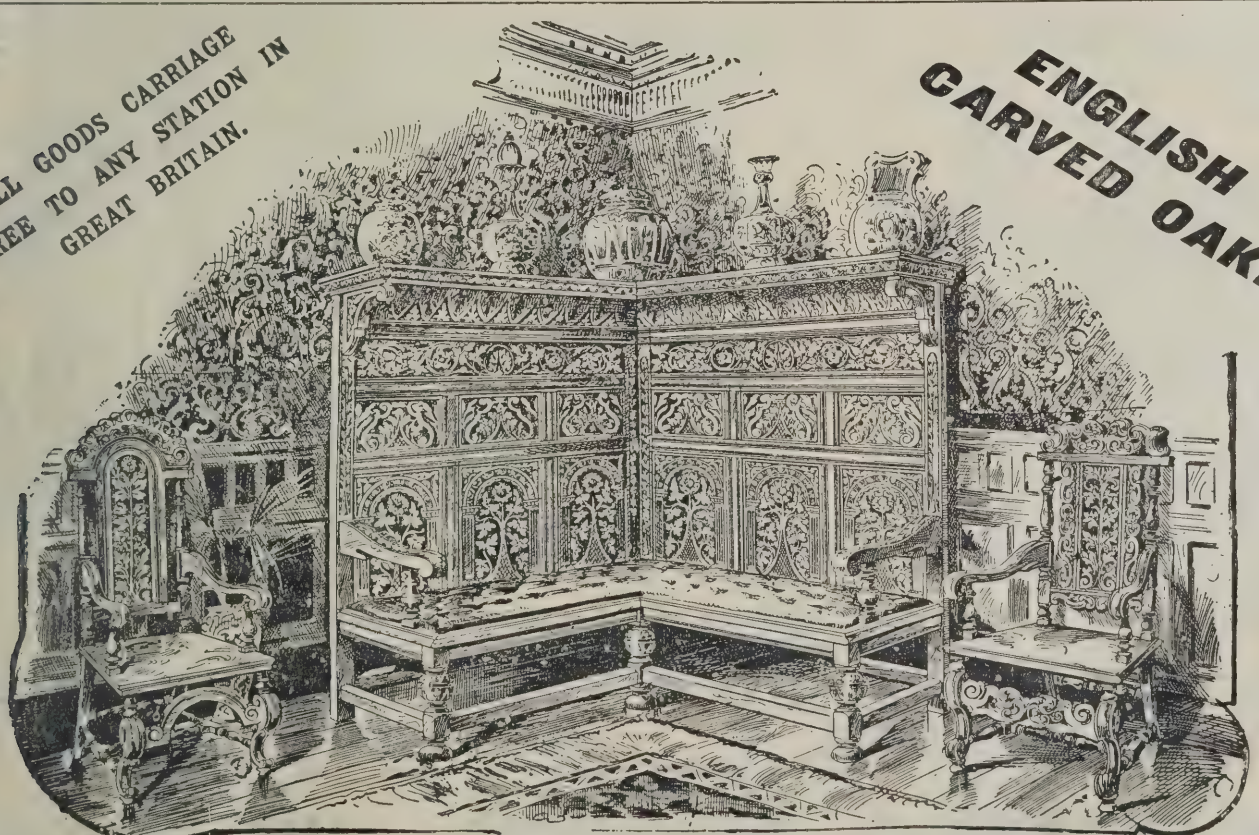
A LARGE-SIZED font was unveiled on the 7th inst. at All Saints Church, Southport. The bowl is octagon in shape and sculptured all round with a band of saints, and stands upon nine coloured marble columns; the centre octagon column is of Victoria red, while the smaller circular ones are of Numidian marble. The bowl, landing, caps and bases are of white Sicilian. The work has been executed by Mr. J. J. Millson, the architect being Mr. Henry Shelmerdine, both of Manchester.

ON the 9th inst. some 8,000 members of the Operative Bricklayers' Society from all parts of London and various counties of England commemorated its jubilee at the Crystal Palace. There were about twenty-six or twenty-eight banners, four bannerets and four brass bands. After luncheon in the saloon the members assembled at the end of the terrace, and formed with their bands and banners into a monster procession, which paraded along the front of the Palace to the rosary, where a meeting was held.

THE London staff of Mr. F. Bedford Pitcher, builder, decorator and sanitary engineer, 46 Fitzroy Street, Fitzroy Square, will join the Walton-on-Naze staff to-morrow (the 16th) for a wayzgoose. The Walton staff is covering an estate with residential villas, temperance hotel, &c., on a three-years' job, and they, with some of the London staff for the rebuilding of the Gordon Hospital, have arranged for a cricket match, *v.* the local Walton team, and some other outings, &c., and as Walton has an East Coast front and bracing atmosphere, they anticipate a very invigorating day.

MR. H. JACKSON, of 134 Westfield Road, Leeds, has sent us a price-list of his patent water boiler, in which the process of heating is effected as the water passes through the boiler, which means a saving in the consumption of gas, and, coupled with many other advantages, undoubtedly places the patent in a favourable position. The boilers are made entirely of copper, and include both gas and water taps fitted with loose unions for easy connection, and the burners are fitted with an improved safety pilot tap for lighting, thus avoiding risk of explosion. The boilers are entirely self-feeding and automatic.

MESSRS. HOBBS, HART & CO. have sent us on a letter which they have just received from Messrs. Slayden & Co., of Wolverhampton, recounting the gratifying result of an accident which befel one of their safes. We think the following paragraph of sufficient interest to deserve quotation :—"Some time ago we purchased a safe of your manufacture from a dealer in this town. It is an expensive one, double doors, we think quoted at 40*l.* on your list, say weight 15 cwt. We wished to move it from the ground floor to second storey, and on doing so, when it was between the second and third storey, the lashing chain gave way and it fell through to the cellar, alighting on its back on a brick floor (say from three storeys high). On applying the key it worked as freely as when it stood in its old position. If you consider the weight of safe and the distance it fell without injury, we think you will agree with us it says a lot for sound workmanship and good material. Not a dent, not a blemish; it simply jerked the knobs off and they broke where the neck screws go into the spindles." Messrs. Hobbs, Hart & Co. inform us that the safe in question was turned out of their works as long ago as 1869.



DANVILLE ASBESTIC plaster has been specified for the new warehouses for the Manchester Ship Canal Company, and the work is now in progress. All the ironwork (consisting of some thousands of girders and columns) is being encased with expanded metal lathing, and protected with Danville asbestic plaster.

THE pens manufactured by John Heath & Co., 70 George Street, Birmingham, of which they have sent us some samples, deserve a word of commendation on account of their agreeable qualities of smoothness and flexibility. They are cheap, too, varying in price from 1*s.* 4*d.* to 3*s.* 6*d.* per gross, and the wide range of shapes suits them to all purposes.

THE forty-seventh annual meeting of the Birkbeck Building Society was held recently at the offices, 29 and 30 Southampton Buildings, Chancery Lane. The report adopted states that during the financial year just closed the total receipts from all sources, taken with the disbursements, discloses the fact that the annual turnover has amounted to 37,488,736*l.*, being a daily average of upwards of 120,000*l* for every business day that the office has been opened throughout the year. The investments now exceed 10 millions—10,778,675*l.*—and the total liabilities on subscriptions and deposits also exceed 10 millions; whilst the balance of assets in excess of liabilities amounts to 441,984*l.* The amount received for subscriptions during the year has reached the sum of 266,511*l.* After allowing for withdrawals, the amount standing to the credit of investing members at the close of the year is

BUILDING AND BUILDERS.

PLANS are being prepared for the alteration and practical reconstruction of the Heckmondwike refuse destructor.

THE men at the Bangor slate yards have struck work through a dispute as to the working hours.

THE contracts for the proposed new Constitutional Club buildings at Farsley have been let, and secured by local contractors. The estimated cost of the building and site is upwards of 2,000*l.*

THE erection of a public slaughter-house in Leeds for the destruction of old horses and superfluous dogs, &c., has been suggested, and a sub-committee of the Leeds Corporation are contemplating taking a trip down south to acquire information on the subject.

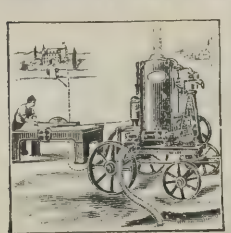
THE Cromer Commissioners have decided to apply to Parliament to borrow 50,000*l.* for the purpose of erecting a pier and other works.

THE plans and works committee of Edinburgh Town Council yesterday recommended the acceptance of the offer of Messrs. Mackenzie Brothers, amounting to 1,358*l.*, for the engineering work in connection with the new Stockbridge baths.

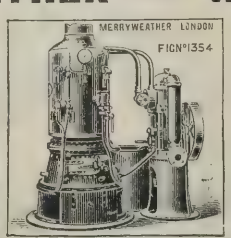
THE foundation-stones were laid last week of the proposed new Wesleyan chapel and Sunday school at Cricklewood, close to the Edgware Road. The chapel, which will contain 745 worshippers, will cost, together with the schoolrooms adjoining, 7,300*l.*

AT a meeting of the Ayr Town Council further discussion took place regarding the question of a new town hall. It was ultimately agreed to ask an eminent architect to report as to the erection of a suitable hall.

THE intervention of the Board of Trade in the Bristol building trade dispute has been successful. Mr. Hudson, Q.C., who was sent down as conciliator, yesterday succeeded in effecting a compromise.



A SITE has been purchased at a cost of 400*l.* for a new church in the parish of Feniscliffe, Blackburn. This parish was formed out of the two adjacent parishes in 1893, when a new church was built and consecrated.



WHAT promises to be, if carried out, a very great improvement in Fenchurch Street is, says the *City Press*, being engineered by the astute deputy for the ward of Aldgate. A large piece of vacant land in Fenchurch Street is now about to be built upon, and the deputy's suggestion is that a fine block of premises should be erected upon it with a view to its forming the headquarters of the shipping and insurance interests in the eastern portion of the City. At present, as is well known, the Baltic, the Shipping Exchange, and various known undertakings are located in different thoroughfares, and, as a consequence, much inconvenience is occasioned. If steps can be taken to bring all these organisations into one building, not only will the public convenience be studied, but a great architectural improvement will be effected, and Aldgate will take another step forward in the direction of becoming one of the most important districts in the "one square mile."

A MOVEMENT has been started to place the parish church of Christ Church, Stafford, in a sound condition. Portions of the exterior, especially the top part of the tower and the guttering and spouting, are in a state of decay. This is the case also with several of the windows. The interior is throughout in a most unsatisfactory condition. The church has been minutely examined by a well-known county architect, and, acting upon his report, a committee of gentlemen have resolved that the work of renovation shall be proceeded with at the earliest date possible. The organ has also been carefully examined by an expert, and has been pronounced to be worn out in many portions and partially collapsed. It has been decided, therefore, that the organ shall be taken down and rebuilt with additions and improvements, so as to make it suitable to the size of the church. The total cost will be about 500*l.*

THE dispute in the building trade culminated on Saturday in a general lock-out throughout Lancashire. The difficulty originated in Bolton and other Lancashire towns. The operative masons asked for a reduction of working hours and for increased pay, and some of them also objected to working stone dressed abroad by foreign workmen and imported into this country. They served notices on the employers stating these terms. The result was that the masters retaliated by serving notices upon a portion of the men, intimating that their engagement under the existing conditions would terminate on Saturday. At first in Liverpool and district these notices were served upon a portion of the operative masons; the remainder

of the men seemed to be content to stay at their work, no doubt intending to help those who were locked out. The masters, however, ultimately served notices of a lock-out upon all the working masons, expiring on Saturday. No settlement of the dispute has been arrived at, and the consequence is that all the operative masons throughout Lancashire have ceased work to-day. At present the building trade is brisk, and it is feared that this dispute will cause much inconvenience and hardship.

VARIETIES.

THE Royal Victoria Cottage Nursing Home at South Ascot was opened on Tuesday afternoon by the Duchess of Albany. The building is of red brick and has cost a little over 2,000*l.*

A STATEMENT has been submitted at the Ayr Town Council meeting as to the cost of the new Victoria Bridge over the river Ayr. The total cost of the bridge was 9,514*l.*

THE formal opening of the Diamond Jubilee organ erected in Ryde Town Hall at a cost of 1,000*l.*, took place on the 11th inst.

IN the building in course of erection on the Hanover Chape site, Regent Street, two small shops have, it is said, been let by Messrs. Knight, Frank & Rutley, of Conduit Street, together with a showroom, at a rental approaching 3,000*l.* per annum.

ON Monday, October 3, at 4 P.M., the Huxley lecture will be delivered by Professor Virchow, director of the Berlin Pathological Institute ; subject, "Recent Advances in Science and their Bearing on Medicine and Surgery." The lecture will be delivered at the Charing Cross Hospital Medical School.

A NEW mission church erected in the Marsh district of Lancaster, at a cost of 2,100*l.*, including site, which is large enough for an extended building if required, was opened on the 7th inst. The church provides accommodation for 300 worshippers and is dedicated to St. George.

INTIMATION was made at a meeting of the Glasgow Town Council of an offer to gift 12,000*l.* for the erection of public halls in the Springburn and Cowlairs districts of the city, provided that the Corporation agreed to spend 10,000*l.* in building a winter garden in Springburn Park.

MOST of the houses and offices of Manila have tiny panes of translucent oyster-shell for glass. An average window is 6 feet long by 4 feet wide, and contains 260 shell panes, which temper the heat of the sun and prevent blindness.

THE hospital recently erected in connection with the Hawkhead Asylum of the Govan District Lunacy Board was formally opened a few days ago. The site of the hospital is to the east of the asylum, and it includes sections for the treatment of recent and acute cases, infectious cases and sick and infirm cases. There are separate rooms for each patient, and accommodation is provided for 144 altogether. With the erection of the hospital the asylum buildings are now complete, the work of construction having been going on since 1891.

THE task of repairing the very extensive damage caused to Spurgeon's Tabernacle by the fire that occurred there on April 20 is in hand as far as the basement of the structure is concerned, and it is hoped that before the end of September this portion of the building, which suffered less than the part above the ground level, will have been reinstated, so that the ordinary services and meetings of various kinds in connection with the Tabernacle may be held there.

THE Midland Railway Company are sending out, free on application, an artistically covered and printed *brochure*, "Travel and Entertainment," which gives the tariffs of the hotels of the Midland Railway of England, together with useful information for all travellers on business or for amusement concerning hotels, refreshment-rooms, dining cars, trays of tea, luncheon baskets, grills, popular restaurants. It contains a list of places of interest in London ; maps of London, Liverpool, Bradford, Leeds, and picturesque views of the company's numerous hotels.

THE new infirmary buildings, which have been erected adjoining the present workhouse at Whiston, were opened on the 7th inst. The new buildings, which have cost about £20,000, have long been needed owing to the growing necessities of the union, and the old infirmary building will be taken up for general workhouse accommodation. The new buildings are of simple brick, and comprise two large blocks of three storeys and two blocks of two storeys each, and have all the most modern appliances, including fireproof floors throughout and fire-escape landings. There will be accommodation for about 300 beds—thirty on each of the ten floors. Mr. Brown was presented by the guardians with a silver-gilt key for the performance of the opening ceremony. The architect of the new

infirmary was Mr. James Gandy, St. Helens, and the contractor Mr. Fred Brown, also of St. Helens.

AT Rotherham on the 7th inst. Lord Deasborough opened the new children's ward at the hospital—to be known as the Queen's Ward—erected in commemoration of Her Majesty's Jubilee. The Queen's Ward contains sixteen cots, and is a handsome addition to the hospital, combined with the improvement which has been effected in the laying out of the grounds. The bathrooms and sanitary blocks are fitted up with the most modern sanitary appliances, which have been supplied by Messrs. Dent & Hellyer, of London. In addition to the large ward, there is a small isolation ward for two beds, fitted with bathrooms. The cubic space allowed to each bed is about 1,200 feet. The walls of the wards are lined with Burmantofts faïence up to the height of 5 feet, and above that the walls are painted Parian cement. The effect of the scheme of colouring is extremely good. The large ward is heated by a central stove in addition to the hot-water pipes. In the small ward there is a fireplace and also pipes. The building has been erected and arranged in consonance with the most modern and advanced ideas of hospital construction. The lighting arrangements are of the best, and the general effect of the rooms is one of breeziness and space. The floors are all laid with tazzo, a species of Italian mosaic. Mr. J. D. Webster, of Sheffield, has been the architect, and Messrs. Chadwick & Co., Rotherham, the contractors.

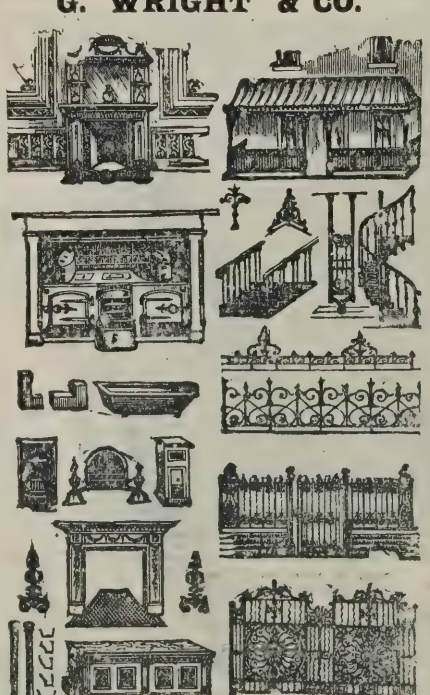
THE ancient church of St. Kentigern at Irthington, near Carlisle, having undergone a careful and complete restoration, was reopened on the 28th inst., on which occasion the new tower and some additional burying-ground were also consecrated. The tower was built from designs from Mr. T. Taylor Scott, architect, Carlisle, at a cost of 1,100*l*. It is a massive red stone structure, with stepped buttresses on all the faces adjoining each angle, and the west side has been very effectively relieved by forming the structure around the stone spiral staircase into an architectural feature with loophole lights. This front has a moulded and pointed arched doorway and massive oak door. At a height of about 30 feet the three principal fronts have been pierced with circular openings about 4 feet in diameter for the clock faces, and on each side of the upper part of the tower there are large double openings filled in with louvres for the belfry. The total height of the tower is about 60 feet, the foundation being at a depth of 7 feet below the church floor. The flag-pole rises to a height of about 25 feet above the centre of the roof.

GUILDHALL SCHOOL OF MUSIC.

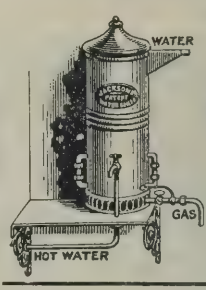
THE Lord Mayor, accompanied by the Lady Mayoress, the sheriffs, Mr. Alderman Green, Mr. J. Dewar and the chief officials of the Corporation, went in state on Monday afternoon to the Guildhall School of Music with the object of opening the newly-erected extension thereof. The new building, of which the site measures 72 feet by 51 feet, has been erected from plans prepared by Mr. Andrew Murray, the City surveyor, and provides a theatre 47 feet wide, 55 feet long and 30 feet high, fitted at the northern end with a stage (possessing an asbestos fireproof curtain and all necessary appliances); there is also a large gallery at the opposite end of the auditorium. Entrances to the theatre are provided from the old school, and in addition to these there are six emergency exit doors, four to John Carpenter Street, two to the City of London School for Girls in the rear. In the basement are dressing-rooms, green-room, &c., all in direct communication with the stage and the older building. Above the theatre are three floors, divided into thirty classrooms by double partitions; each partition is formed of hollow blocks, which arrangement is intended to prevent the passage of sound from the various rooms. For a similar reason the floors are framed independently of walls, partitions and ceilings. The constructional portions of the floors are of iron and concrete. The warming is effected entirely by hot-water radiators, which are also utilised for the introduction of fresh air. The vitiated air is withdrawn by means of extractor trunks connected with the upcast shaft from the furnace.

THE RENEWAL OF ELECTRIC LAMPS.

By F. J. WARDEN-STEVENS, A.M.I.E.E., &c.



IN this article I propose to deal only with incandescent lamps, viz. those used mostly for interior lighting. Incandescent electric lamps, unlike gas burners, are made in so many different forms that it is essential something should be known about them.



Now with an ordinary gas burner, all we want to know is the light it is to give, which depends roughly on the number of cubic feet it passes per hour. With an electric lamp we want to know what pressure circuit it is to be used on, what is to be its efficiency and what its candle-power. A gas burner is fitted and little more is thought of it until perhaps it is found to be corroded or blocked with dust, and then it is renewed. With

an electric lamp it is generally used until either the filament or bulb breaks.

I propose here to point out the advisability of a little further consideration of the matter. I will not go into the question of the manufacture of an electric lamp; suffice to say that it consists essentially of a carbonised cotton filament enclosed within an airtight glass bulb. As before mentioned, electric lamps are made for use on circuits of different pressure; this is owing to there being no fixed standard pressure of supply, consequently we have current supplied in different districts at 100, 102, 105, 110, 115, 150, 200, 210, 220, 230, &c. volts pressure. The higher the pressure used the lower is the current required and therefore the size of the filament.

Now, with regard to the efficiency of a lamp, one taking less current and giving the same illumination is certainly more economical as regards the lighting bill, but we have another fact to consider, and that is the life or length of time the lamp will last. A lamp consuming less current than another with the same quality filament must have a thinner filament if giving the same candle-power at the same pressure, and this filament must be at a higher temperature. If we were certain of the pressure always being constant, the life of the lamps would be considerably prolonged; but, unfortunately, this is not so, although the Board of Trade, according to their regulations, limit the variation to 4 per cent. either way. If we are using a high efficiency lamp and the pressure is increased, this means still further increasing the temperature of the filament, and such strains reduce the life in a greater proportion than with a lower efficiency lamp. But for the variation of pressure high efficiency lamps would be used to a far greater extent.

Coming to the question of the amount of illumination given by the lamps, few lamps give exactly their rated candle-power even when first used, and they gradually fall off with use from several causes. The blackening of the bulb few have failed to notice. This blackening and therefore decrease in illumination is due to the disintegration of the carbon filament which coats the interior of the bulb with the carbon dust. The disintegration causes a pitting or unevenness of the filament which increases the area, and therefore decreases the temperature and light still further. The light is also again further decreased, due to the temperature being again decreased by the increase in resistance of the filament. The variation in pressure before mentioned as affecting the life also affects the candle-power of the lamp, but the candle-power varies in far greater proportion than does the pressure. I think, however, that the actual candle-power is of no great moment to users as long as they are getting sufficient illumination.

Reverting to the question of length or use of a lamp. It has been proved from exhaustive tests that electric lamps have many peculiarities. For instance, some have a high efficiency at first, but this falls off quickly with use, as also does the candle-power. Some last for about 1,000 hours, whereas others only last 500. Yet others maintain a fairly constant light throughout their life. Going into the consideration of actual practice we find that little thought is given to the purchase of electric lamps, those which last a long time being preferred. This, however, has been proved to be false economy, as the consumption of electricity and the blackening increase with the life of the lamp, and, therefore, if the cost of electricity is high it is better to renew a lamp before it breaks.

The cost of electric lighting is proportional to the cost of electricity, plus the cost of renewing the lamps. Now to insure a minimum it is necessary for the lamps to be tested, which the user is unable to do. A company has, however, come forward with a system which, I think, will be admitted is a great benefit. This company not only guarantees the life of the lamp but the economy also.

It may be as well to briefly mention the system adopted. The lamps are ordered to a strict specification, and no special make of lamps is used; when received they are placed into the store in racks, from there they are passed to the testing-room, where they are examined individually for external soundness as regards bulb, socket and filament.

A proportion of the lamps then go through an "ageing" test, which is intended to show the lasting qualities of the lamps. These are first carefully tested for candle-power and efficiency at the normal pressure, and the pressure applied to the lamp terminals is then gradually increased to a certain percentage, varing from 25 to 100 per cent., with different lamps above the normal. They are then re-tested for candle-power and efficiency, which must not be less by more than a certain percentage. If they are, the whole batch of lamps are rejected. If they pass this test, then each lamp must be up to a certain standard of candle-power and efficiency; all that do not pass this test are rejected, and new ones must be supplied by the makers. Those which pass these tests are stamped with the company's mark and are placed in stock.

By this means it will be seen that this company is able to supply lamps which are certain to give satisfaction and to be

PATENT

VULCANITE ROOFING.

Since the introduction of the patent Vulcanite Roofing into this country it has been adopted by a great number of leading architects for Public and Private Buildings, Hotels, Schools, Hospitals, Theatres, Mills, Warehouses, Breweries, Shops, Villas, Dwelling-houses, &c.

The temperature of the rooms immediately beneath the roof is more even in winter and summer than under any other roof. When properly laid repairs are never required, and all roofs are guaranteed. The roof-surface can be used as a garden, or for any other purpose. The cost of construction is less than even for a slate or tiled roof.

SHEET ASPHALTE for DAMP-COURSE, WATERPROOFING VAULTS, BRIDGES, TUNNELS, &c., is manufactured ready for use in lengths of 40 feet, and any width up to 40 inches, being more convenient than the usual damp-course slabs, and saving laps. Price lower and quality much superior to any similar article in the market.

SHEET ASPHALTE for ROOFING SHEDS, LIGHT BUILDINGS, &c., and for SARKING under slates or tiles, manufactured in five different qualities and in rolls of 15 superficial yards. It is easily laid, very inexpensive, much superior to felt roofing, and requires no annual coating.

Full particulars, Catalogues, Detail Sketches, Estimates, re Vulcanite Roofing; Samples, Prices, &c. re Sheet Asphalte, free.

Vol. LVIII. of THE ARCHITECT. Handsomely Bound in Cloth, Gilt Lettered, Price 12s. 6d. Office—175 Strand, London, W.C.

economical. To prove that these lamps are better than those supplied in the ordinary way, it may be said that nearly all the manufacturers tendered for the first batch of lamps to pass the company's tests at a price considerably above the ordinary trade price, although a large quantity were purchased.

From stock the lamps are placed in special baskets, and are delivered to the clients of the company, each client having a special box in which to keep the lamps. If a lamp fails a new one may be taken from the box, the old one taking its place, the stock being renewed periodically. A charge is made for the lamps on the following basis.

Every lamp is supposed to last 500 hours before its candle-power decreases and the efficiency becomes less than a certain amount. The average hours of use is arrived at by an inspection of the meter book and the maximum current the lamps take when all are in use together. One lamp per 500 hours is charged for, and all that are required are supplied without any extra charge.

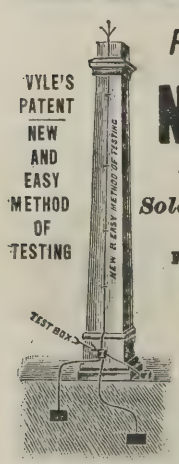
Periodically all the lamps on the premises are re-tested, and all not up to standard replaced. It may be of interest to state that by means of this company's system a saving of from 10 per cent., and even more, can be effected in the cost of electric lighting. The secret of the whole system is that a large buyer can insist on having what is required, and, if tests are carried out, obtains it. A small buyer must have what is given him, and in the case of lamps has no means of testing them. The result is that he obtains low efficiency lamps, which are easier to make, or lamps of very uneven quality.

It may be said that the makers test all lamps, but it is a fact that only a few are really tested properly. A photometer is an instrument which enables the ratio of the candle-power of a lamp to be arrived at. At the same time the power taken by the lamp is measured. Now, in most factories only a few lamps are tested on the photometer, the rest are compared with these by eye, and as a result they are uneven; some are bright and others dull when on the circuit.

The company above-mentioned have fitted up a laboratory in which no expense has been spared to enable lamps to be accurately tested. The current is supplied from a battery of accumulators charged from the public supply mains. Any pressure can be taken from this battery at will. The photometer is of a type which is peculiarly adapted for rapid and correct testing, and all the measuring instruments are of the best.

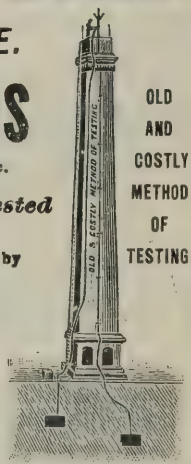
The standard of light used is the Vernon-Harcourt Pentane giving 1 candle-power, but it is not used except to occasionally standardise an electric lamp of approximately the same candle-power as those on test. It is found to be more convenient and to a great extent more accurate to very carefully standardise an electric lamp than to use the 1 candle-power standard always, it being easier to compare, say, a 16 candle-power standard with another 16 candle-power than with a smaller unit, and also any variation in pressure on the testing circuit will affect both the standard and the lamp being tested, preventing the error which would arise if one were electric and the other an oil standard.

This company is also prepared to supply tested lamps with a certificate of their quality to contractors, builders, architects and others who might not care to adopt the guarantee system. This plan should replace the present practice of buying lamps, as the certificate of the company is a guarantee and the convenience apparent. Also, if purchasers of lamps require their lamps tested, the company undertake this at a small charge and gives a certificate of the result.



I think that this company will be of great use to architects, builders and others who have to consider electric lighting, and they will be certain to effect a saving in cost by adopting one or other of the alternatives offered.

Those desiring further information on the matter will no doubt have all inquiries answered addressed to the Secretary, Electric Lamp Contract Renewal Company, 15 Victoria Street, Westminster, S.W.



BUILDING SITES IN JAPAN.

A MEMORIAL signed almost unanimously by the British residents at Kobe and Nagasaki has been addressed to Lord Salisbury, directing attention to the disabilities and dangers to which they state they will be exposed under the treaty with Japan which is to come into operation on July 16, 1899. The advantages which were supposed to have been gained for British subjects in return for the surrender of extra-territoriality are, it is urged, nullified by the defects of the new arrangement. Thus in the matter of land tenure, no British subject or other foreigner resident in Japan may buy or own a single rood of Japanese soil, and although it is provided that British subjects may lease land for residential and commercial purposes the period of such leases is limited in the new code to twenty years. The absurdity is pointed out of supposing that British subjects will build workshops or other premises which at the

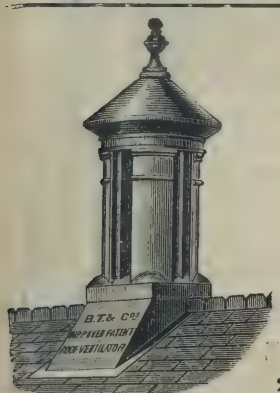
expiration of so short a term of years may pass out of their hands or be subjected to an impossible rent, especially in view of the fact that the standard of commercial morality in Japan is not such as to afford very satisfactory assurances as to the policy likely to become prevalent among Japanese landowners in such circumstances.

WATER GAS.

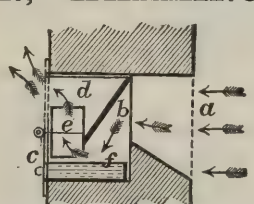
THE public control committee of the London County Council have received a letter from the departmental committee of the Home Office, which is considering the questions of the manufacture and supply of water gas, asking for the opinion of the Council on the subject. The public control committee now report that, having carefully considered the matter, they have come to the following conclusions, which they have communicated to the departmental committee:—(1) That considerable danger arises from the introduction of water gas in the process of the enrichment of coal gas; (2) that non-carburetted and non-odorised water gas should not be allowed to be used under any conditions, since it is devoid of smell, which would give warning of any escape of the gas; (3) that 25 per cent. should be the maximum amount of water gas allowed to be introduced in the enrichment of coal gas, the proportion of water gas being ascertained by determining the amount of carbonic oxide in the enriched coal gas (coal gas enriched to this extent would correspond in poisonous character to the Dowson gas, which is already in use for heating purposes and for gas engines, and would exclude the use of carburetted water gas); (4) that when it is proposed to supply poisonous enriched gas to houses and the interior of buildings a proper inspection be made of the service pipes by a responsible officer appointed by the local or other suitable authority, who should certify that the pipes are in a sound condition and that there is no escape of gas, and that the cost of such inspection be borne by the gas company.

LONDON AS IT IS.



IN an article in the *Contemporary* on "Ideal London," Mr. Frederic Harrison says:—It is the weak side of modern civilisation that it has failed to carry on some of the fine elements of city life as known to the ancient and Mediæval world, and of all Europeans, we English of to-day take the least pride in our cities and receive from them the least of inspiration and culture. The historic cities of the world—Jerusalem, Athens, Rome, Byzantium—sum up entire epochs of civilisation in themselves. To the ancients the very idea of a nation, with a national system of life, implied a mother-city as its home and type. And in the modern world the citizens of Florence, Venice, Paris, Seville, Bern, Nuremberg, Bologne and Ghent have all had far deeper sympathy with their native cities than the Londoner has with his city, at least within the last two or three centuries of its life. This is a definite loss to London and to England. For if we truly estimate the indispensable need to a nation of a great capital worthy of itself, as a seat of its highest culture, energy, organisation, we shall see that England and the British race are all the poorer in that London fails to inspire the Englishman with that sense of sympathy, pride and example which Rome gave to the Roman world and which Paris gives to the French and the whole Latin race.

To the poor countryman London is too often a place where he may get busy life, variety and cheap amusement. To the rich countryman it is a place where he goes to buy all things that money can furnish; where Vanity Fair lasts for some three months, and from which he rushes off when his purchases are made and when the fair is over. To the dull provincial it is a place where he hopes to pick up "the last thing out"—in the peculiar vernacular he affects. To the ambitious man of business and the aspiring professional it is a place where toil and energy and skill may enable him to make a fortune, and in old age to retire to a rural retreat with an adequate "pile." And the city suffers, both within and without, from these unworthy aims, and it has the aspect of a place which is valued mainly as a market, an exchange, a warehouse, an office and a playground. It was not thus that Athens, Rome, Florence and Venice were looked on by their citizens, nor was London so looked on in the age of Norman and Plantagenet, of Tudors and Stuarts.



PHILIPPINE HOUSES.

ACCORDING to Professor Steere, earthquakes, the usual accompaniment of volcanic activity, are too common in the Philippines to be remarkable, unless they tumble one's house about his ears. The light, basketlike dwellings of the natives, perched

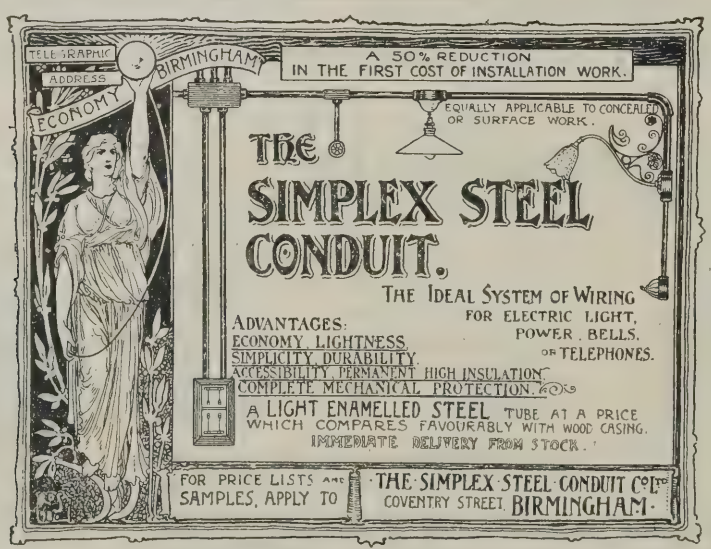
upon posts, sway about like cradles during these strange movements of the earth, and are often thrown out of perpendicular, but are rarely destroyed.



The stone buildings of the Spanish, though usually built of light volcanic rock or of coral, and with thick walls and low storeys and projecting buttresses to protect them from earthquakes, are frequently thrown down. Spanish Manila, the old walled town, the only city in the archipelago built of stone, has suffered most, and some of the streets are still blocked by the ruins of the great earthquake of 1880. In 1863 the city was nearly destroyed, and at frequent intervals since its foundation it has suffered loss of life and property.

In the provinces buildings of stone are rarely found, those existing being generally the churches and conventos, or priests' houses. These have been built by the untrained natives and with no other architects than the priests themselves, but are strongly built and rarely fall. Several times, while being entertained by these hospitable priests, we have been startled by the cry of "Temblor!" when all would rush out of doors, to be out of the way of falling walls, and, after a few minutes' waiting, would return to take up our dinner or conversation where we had left it.

THE WATERLOO AND CITY ELECTRIC RAILWAY.

THE new Waterloo and City line was opened for traffic on Monday. It is one of the smallest but most interesting of railway enterprises. It is about a mile and a half long. It runs from the Mansion House along Victoria Street, plunges down under the Thames at Blackfriars, comes up on the other side, runs along Stamford Street, across beneath the Waterloo Road into the York Road, and terminates right down in the roots of the great Waterloo station. There are two separate tunnels practically the whole way. They and the two terminal stations have taken about three years and a half to construct, and the cost—apart from equipment—has been, says the *Daily News*, something over half a million of money. No small portion of this sum must have been expended on the works underneath Waterloo. The building of the station here looks as though it must have been a far more serious undertaking than the straightforward job of pushing the two lines through the solid London clay beneath the river bed. Carried out on the Greathead shield system, that has been a tolerably safe and easy process. The queer, subterranean station at Waterloo looks to have been a perilous and gigantic task, and it has been even more gigantic than it looks, for a vast amount of the work here has consisted in the "underpinning" of the supports upon which the great station, with its trains and engines and crowded platforms, have rested.

The station thus constructed seems, with its approaches, to stretch out to as great an extent as that of the South-Western overhead. Long white-glazed brick galleries stretch away from the busy upper world of smoke and sunshine down into this nether world of electricity and the dull thunders of the traffic overhead. The white-walled, electrically-lighted passages referred to lead in by easy downward slopes from the roadways north and south and from the platforms of the upper station. There will be no booking-offices and no day tickets, though season tickets will be issued. Passengers will pass down the inclines, pay their fares, and pass through a turnstile, just as they do on the City and South London. From this it will be inferred that, also like the City and South London, there will be but one class. The trains, however, will be very different. Each will consist of four coaches. There will be no engines in the ordinary sense of the word. Each end coach will have an electric motor constituting part of it, the foremost and the hindmost seat in the train being raised up above the electric mechanism. Each train will thus be self-contained and complete without the appendage of any locomotive. This obviously will simplify the management of the traffic very greatly, as there will be no detaching engines from one end of the train and shunting them for attachment at the other. The coaches will be entered by gangways somewhat after the manner of the South London electric line, but the seating is differently arranged. Instead of the seats down the sides they are for the most part arranged across the floor of the car, with a passageway down the middle, two seats being on either side. In each car there are, however, a dozen seats—six on each side—arranged the other way, their backs to the wall so to speak. The two end motor cars have seats for forty-six passengers, the two inside ones holding rather more. Each train of four carriages will hold somewhere about 200 passengers seated. At busy times, however, the Waterloo and City will be managed on much more severely virtuous principles than most metropolitan lines if they don't get another good hundred into each of them. These new trains are American handiwork, and in their form, their style of building, their strength and solidity and the democratic severity of their appointments, they are quite novel in this country. There are no curtains or

cushions—unless the company relent somewhat and mitigate the Spartan rigour of their interiors with slight mats for the bare seats. They are built of solid oak or something closely resembling it, and from the bottom of the window level the sides slope inwards like some of the saloons of river steam-launches. This is in order to adapt them to the circular walls of the tunnels they are to run through. The wheels are exceptionally small, and the carriages, therefore, ride very low, and they are broad at their base. This lowness and breadth and the solidity of their construction, and their tapering form upwards, give them an appearance of massive strength quite unlike anything hitherto seen on our lines. They are severely utilitarian in their finish, but their sound timber, merely varnished, their good plate-glass and first-class workmanship in all their details render them handsome and attractive, and unless very emphatic promises are unfulfilled they will be exceedingly well lighted by incandescent electric lights.

This rolling stock has been brought in on the South-Western line above and has been lowered down upon an enormous hydraulic lift just under the north side of Waterloo station. This lift is worked by hydraulic power, and will be used for bringing coal to the generating station. The electric generating station is on the south side of Waterloo, between Aubin Street and Lower Marsh. There is a repairing shop here, also with another smaller lift, by which, if necessary, the rolling stock may be brought up from the line below. From the generating station the current will be conveyed to the train motors by means of an insulated central metal, and it will be returned through the rails on which the trains run.

There is nothing intermediate between the Waterloo terminus and the City, where the station arrangements are in some respects only temporary. Eventually the way into the station will be from the central subway and from the Bank station of the Central London Railway. But neither the railway nor the subway is in a stage that permits of this connection, and access to the City end of the line is at present by rather a precipitous flight of steps leading down from the corner of Walbrook. From the bottom of the steps a long incline leads down to the platform, from which a service of trains, at the moment of writing not definitely arranged, will run, but which will no doubt vary according to the time of day. As it is a straightforward rush from one end to the other, and each train travels in its own tunnel, there need be no stopping when once started, and as there will be no shifting of engines, there need be no delay in the return. Trains can then be running at busy times every three or four minutes if required. At other times of the day no doubt they will be less frequent.

The railway has been constructed under the supervision of Mr. W. R. Galbraith, of the firm of Galbraith & Church, and the late Mr. Greathead. The latter gentleman died at the end of 1896, and was succeeded by Professor Kennedy. The whole of the tunnels and the City station were constructed by Messrs. Mowlem & Co. The Waterloo sub-station and the generating station were constructed by Messrs. Perry & Co.

CAST-IRON PIPES.

THE following suggestions for specifications of cast-iron pipes were read before the American Waterworks Association by Mr. F. D. Wanner:—

1. The metal used should be a No. 2 X or No. 2 plain foundry iron remelted in a cupola or air furnace, and of such quality and mixture as will produce a strong and even-grained pipe or casting that will drill and cut readily, and possess a tensile strength of at least 16,000 lbs. per square inch.

2. Pipe should be cast vertically in dry sand moulds truly cylindrical in shape, uniform in thickness of metal, in sections of 12 feet exclusive of bell, with bell end down. The seat or shoulder of the bell and the spigot end should be even. It is conceded in the art of pipe-making at this time that they should be cast vertically for obvious reasons, such as greater solidity, regularity of metal and less chance of air bubbles and of dross remaining in the pipe. They should also be cast with bell ends down, as this will produce a more perfect head, more shapely in form and of greater regularity in depth of socket and metal. Definite action in the specifications on this point would be of advantage to pipemakers, and save them the expense of maintaining a double complement of fixtures. Some engineers are determined, others indifferent, as to this practice. While perhaps a majority of the specifications call for bell ends down, many of them are not enforced, and in the majority of such instances the pipes are cast bell ends up as a matter of economy and convenience to the pipemakers.

3. The depth of socket or bell, with a suitable V-shaped lead ring, should be from 3·5 to 5 inches, according to the diameter or size of pipe; joint room or lead space from five-sixteenths to one half-inch, with number, year and initials of the manufacturer cast in raised letters and figures upon each pipe or special.

THE WELL-KNOWN FRIEZE,
ENTITLED
"THE CORN FIELD."
1. Ploughing. | 3. Mowing.
2. Harrowing. | 4. Carting.
5. The Products of the Corn Field.
Length, Fourteen Feet Seven Inches by Fifteen Inches deep.
A SPLENDID EXAMPLE OF COLOUR-WORK IN PERMANENT INK PHOTO, BY
M. PAUL ALBERT BAUDOIN.
This magnificent Illustration was presented to the Subscribers to "The Architect" in 1886. A few Proofs were taken, which immediately became out of print.

OPINIONS OF THE PRESS.

"We are not surprised to hear that there has been a great demand or the beautiful reproductions of the well-known frieze by M. Pau Albert Baudoin, entitled 'The Corn Field.' The plates have been reproduced by subscription at half a guinea the set, and so great has been their success that a second edition is being issued."—THE LADY'S PICTORIAL.

"They are beautifully done in colours by the permanent ink photo process, and form a very artistic and pleasing set at tue extremely moderate price of half a guinea."—THE STAGE.

"The well-known frieze entitled 'The Corn Field,' which is a splendid example of colour-work in permanent ink photo, by M. Paul Albert Baudoin, is to be reproduced by subscription of half a guinea a set. They are exceedingly artistic, and would grace the walls of any house."—THE GENTLEWOMAN

AND NUMEROUS OTHERS.

In consequence of the almost daily demand for these Plates, they have been reproduced by Subscription at Half a Guinea the Set, and are now ready for issuing.

May be had framed in Solid Oak Frames with Mounts, at Three Guineas the set of Five Plates.

4. The thickness of metal, weight of pipe, with a fair allowance for variation, say from 3 to 5 per cent., should be regulated by the head or pressure to which the pipe is to be subjected, and correspond to the drawings and instructions of the engineer, who should always endeavour to remain on the side of safety, and not forget that it is but small economy, especially during these low prices of pig-iron, to recommend light-weight pipe even for the lightest pressure.

5. The pipe and castings, after coming out of the foundry, should be thoroughly cleaned inside and outside, chipped nicely and then carefully inspected with a light pick-hammer for that purpose. After this inspection the pipe and specials for water should be properly heated, and while hot dipped into a suitable preparation of coal tar mixed with a sufficient quantity of dead oil to give it the requisite body and gloss; the coating, after it is applied, should become hard and tenacious and show no blisters or flakes. The coating on pipe and specials, while an important feature in the trade, is of easy attainment with the proper materials and management.

6. Pipe should be tested by a machine built for that purpose under hydraulic pressure of from 100 to 300 lbs. to the square inch, according to the use intended, giving the pipe while under this pressure a few slight raps with a light iron or wooden hammer.

7. After testing the pipe they should be weighed, and the weight of each marked in white lead, either in the bell or on the outside. Pipe and castings should be sold by the lb., or the legal ton of 2,000 lbs. There is no so-called gross ton of 2,240 lbs. for pipe or castings, and it can be made obligatory only by special contract in writing. This ton should not exist at all, and there is no reasonable excuse for its maintenance by anybody whatever. It is annoying alike to the buyer and the seller, as well as to the railroad companies and other carriers. It is a nuisance that should have been abolished long ago.

8. Time for the beginning of shipment of pipe, quantity per week or month and time for completion should be plainly stated in contract, and without penalty for non-performance of contract on time, because it cannot be enforced at law; and why, then, encumber the contract with it or attempt to frighten the souls of the contractors?

9. Terms of payment should be thirty days cash, unless otherwise agreed, after the delivery of pipe and castings, less 10 per cent. to be retained until the satisfactory completion of the contract.

10. A bond may be required in from one-fourth to one-half of the amount of contract, with sufficient security, rendered by a surety company wherever the same may be practicable.

Parties inviting proposals or bids for pipe and special castings should refrain from asking for bids made on their own proposal blanks or for cash or cheques, because this practice is not binding and is against the policy of law, of no service to them and frequently annoying and a hardship to the bidders, who are, in any event, dependent upon the favour and tenderness of those inviting them to bid under the invariable reservation or right "to reject any and all bids."

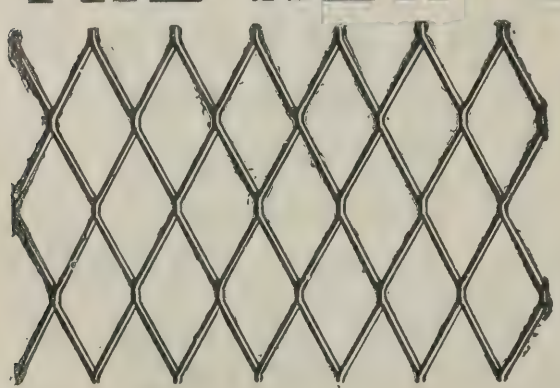
Special castings should be cast upright or on an incline in dry sand or loam moulds, though small specials with care and good management may be cast successfully in green sand moulds.

The fault in specifications too often, outside of provisions that are unreasonable and cannot be fulfilled, lies in their being drawn too rigidly against the contractors and manufacturers, who are treated and seemingly looked upon in the outset as if they were both dishonest and incompetent.

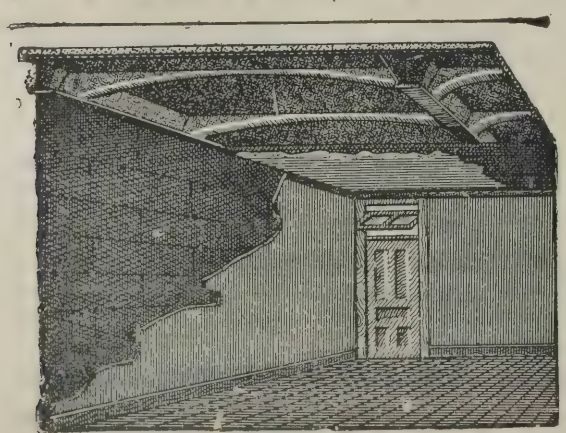
PATENTS.

[*This List of Patents is compiled specially for this Journal by Mr. G. H. Rayner, of the firm of Rayner & Co., Consulting Patent Agents, 37 Chancery Lane, London, W.C., from whom all particulars and information relating to Patents may be had gratuitously.*]

APPLICATIONS FOR PATENTS.



14152. Mark Polhill, for "Scaffold to be used wherever scaffolding is used for all purposes."



14447. Gustav Baader, for "An improved louvre ventilator."

14654. Wilhelm Heinrichs Barmen, for "Improvements in brick-kilns."

TO INVENTORS.—Patents for Inventions, Trade-marks and Designs secured; every assistance given to inventors. Specialists in Building matters. Information free.—Messrs. RAYNER & Co., Patent Agents, 37 Chancery Lane, London, W.C.

THE NEW EXPANDED METAL

Meshes from $\frac{1}{8}$th in. to 6 in. wide. Strands from 24 B.W.G. to $\frac{3}{16}$th in. thickness of steel.

FOR BUILDING CONSTRUCTION, as supplied to a large number of important Buildings, both Public and Private, in this country and abroad.

FOR SOLID PLASTER PARTITIONS, 2 inches thick, with Expanded Metal Lathing. Fireproof, vermin-proof and practically sound-proof.

FOR FIREPROOF LATHING, for attaching to wooden joists and studs, for walls and ceilings, also for suspended ceilings, ornamental mouldings, encasing columns, girders, &c.—no cracking or falling away of plaster to be feared.

FOR CONCRETE FLOORS WITH EXPANDED METAL.—The remarkable results and advantages of these will be better understood by perusal of the Report hereinafter referred to.

FOR EXTERIOR WALLS OF BUILDINGS.—Cement applied to Expanded Metal is not liable to crack or fall away through changes of temperature.

FOR FENCING, TREE GUARDS, WINDOW GUARDS, as supplied to the Royal Parks, leading Railway Companies and landed Estates throughout the Kingdom.

ORNAMENTAL. STRONG. CHEAP.

OTHER USES FOR EXPANDED METAL.—These are innumerable. It can be used wherever lattice-work is required, from a letter-rack to a lift-shaft, for garden bordering and archways. Is highly ornamental and exceedingly durable, having no joints to rust away.

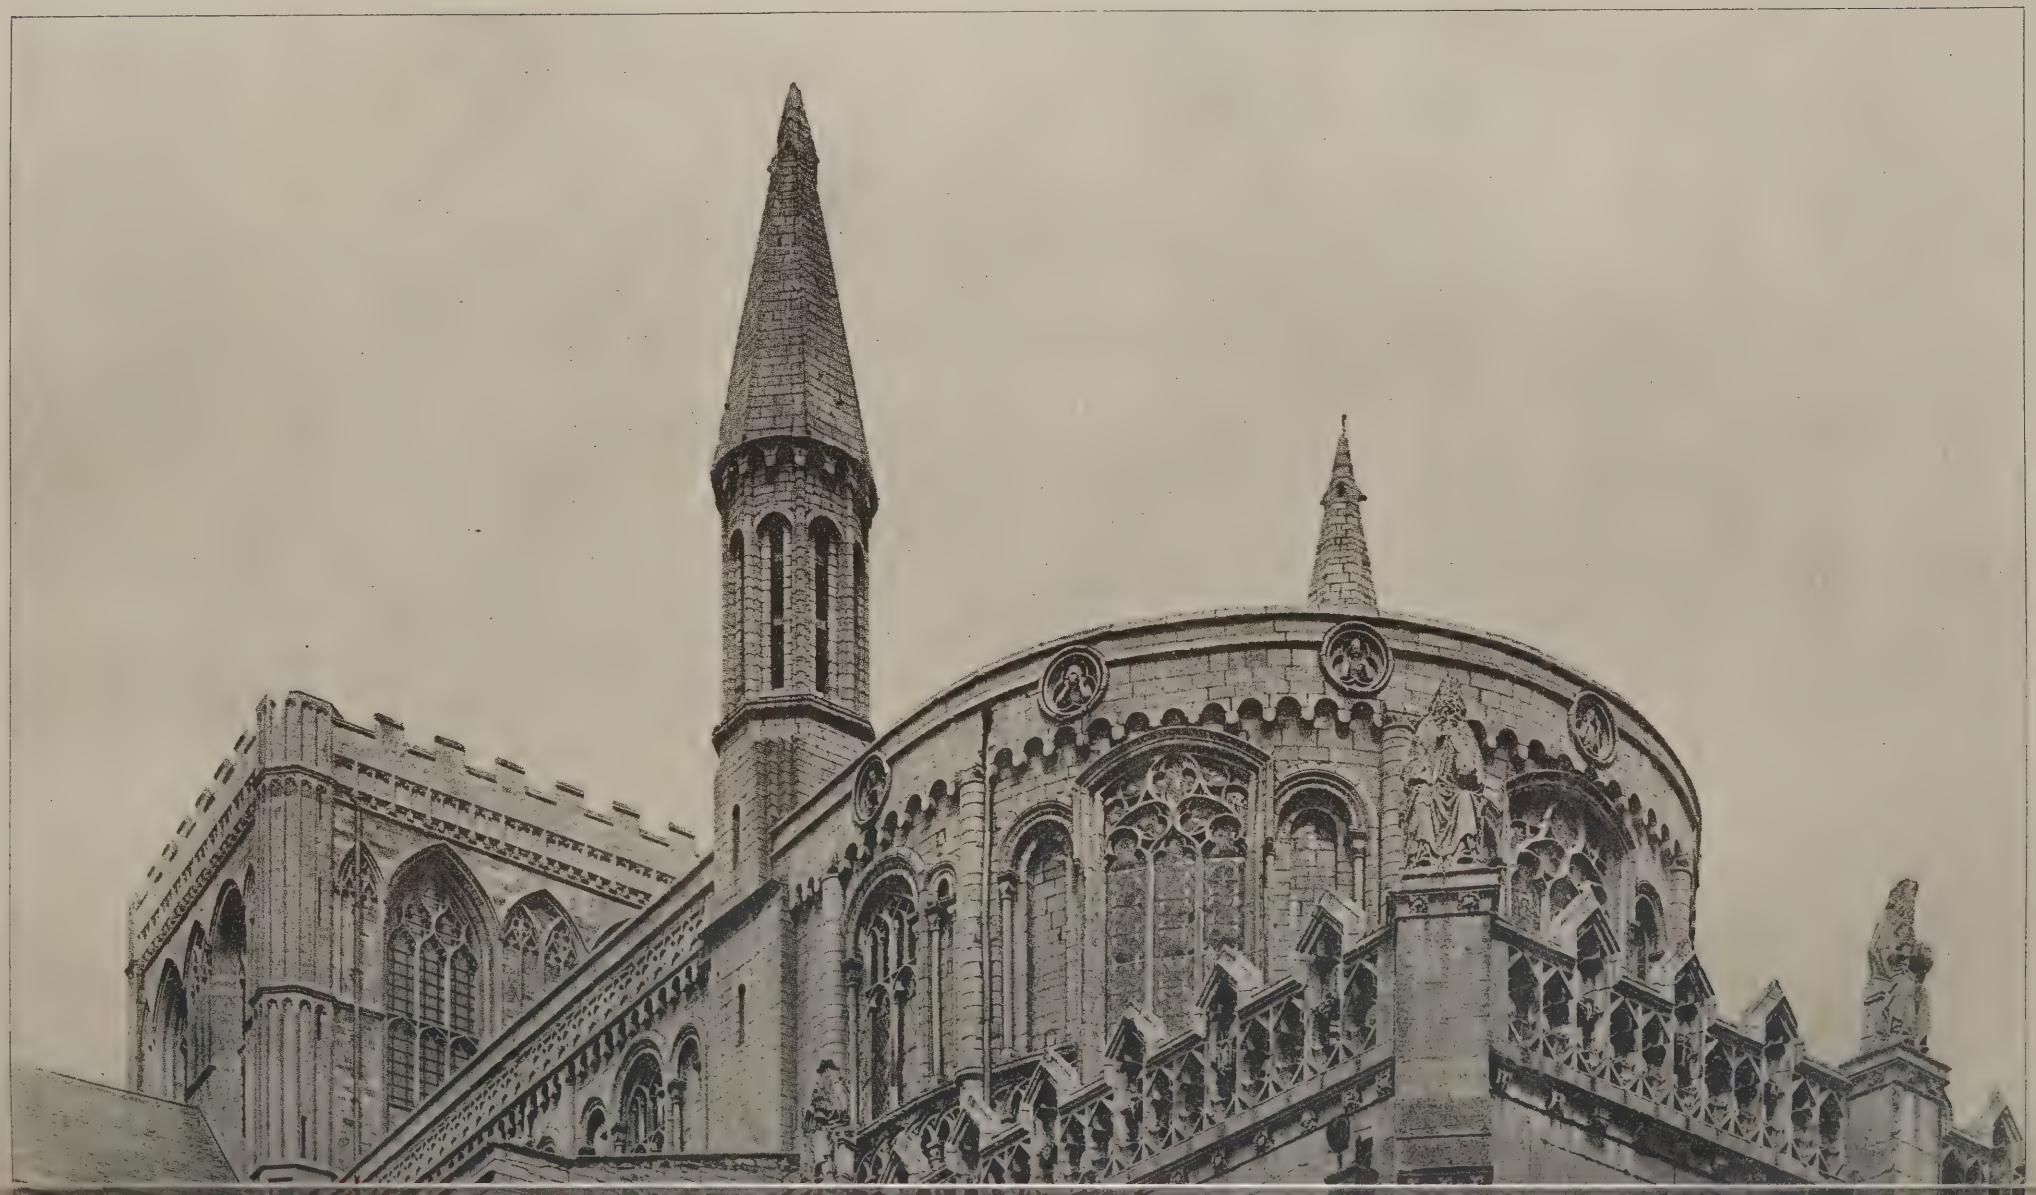
Being expanded by rapid machinery it is considerably cheaper, strength for strength, than any other description of metal lattice-work.

BRASS, ALUMINIUM, or any other ductile metal can be expanded, and the effect is very pleasing, and here again the absence of joints gives great durability to the metal, and the rapidity of manufacture allows of very low prices.

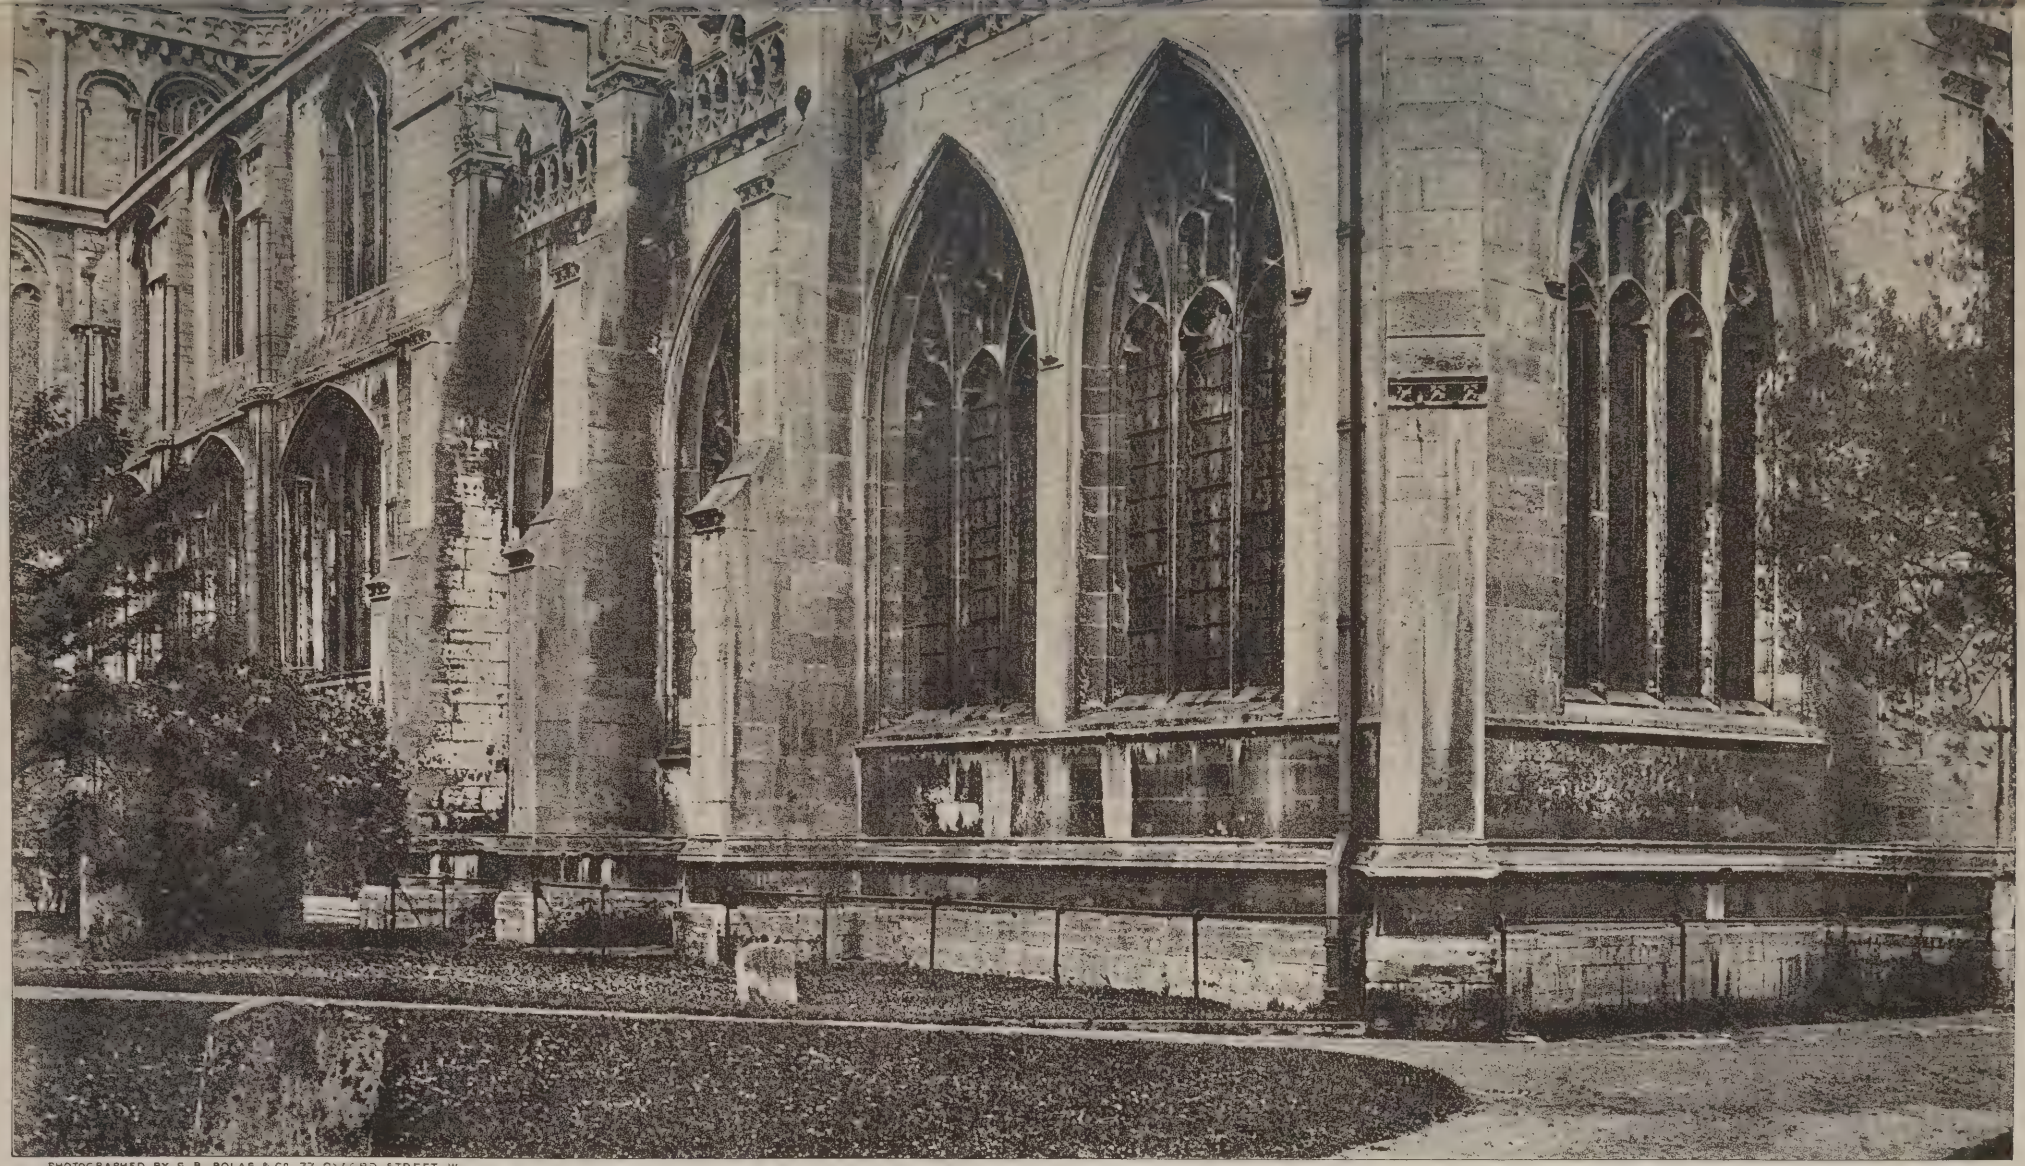
CATALOGUES AND PRICE LISTS can be obtained on application. Also copy of a REPORT by an EMINENT FIRM of ENGINEERS on the use of EXPANDED METAL IN CONCRETE.

THE EXPANDED METAL COMPANY, LTD.

39 UPPER THAMES STREET, LONDON, E.C.



Telegraphic Address, "Distend, London." Works—WEST HARTLEPOOL. Telephone No. 1829.



PROPOSED FAÀ-DI-BRUNO MEMORIAL SCHOOLS, ST. MARY OF THE SEA, HASTINGS.

PROPOSED NEW ROOF AND DECORATION TO THE GUARDIAN ANGELS' CHURCH, MILE END.

J. H. EASTWOOD, A.R.I.B.A., Architect.

The Architect.

THE WEEK.

THE works committee of the London County Council must look upon Mr. MICAWBER as their patron saint and model. Such a band of sanguine men does not exist out of Spring Gardens. The losses inflicted on the unlucky ratepayers of London would be more than enough to make ordinary authorities doubtful about the advantages of amateur building, but the more unfavourable the difference between the outlay and the estimate the more hopeful are the committee about something turning up in the next job to make affairs assume an appearance of being satisfactory. This week the works committee have turned towards a venture on a big scale. It was proposed to undertake the erection of the Horton Manor Asylum, Epsom, without the intervention of a contractor. The official story runs that at the end of March last the manager of the Works Department submitted an estimate of 284,445*l.* for the work. This estimate being higher than the quantity surveyor's and the architect's, and the finance committee not being favourable to the work being carried out by the Works Department, the asylums committee invited tenders, but the lowest tender received was over 12,000*l.* in excess of the price named by the works manager. The works manager being still prepared to carry out the work for 284,445*l.*, the committee recommended that it should be entrusted to him. On Tuesday, when the subject was brought up, Lord WELBY pointed out that the finance committee considered the job was too big to be undertaken by a Department that was only lately reconstructed, and, as Lord ONSLOW afterwards added, the finance committee was practically the works committee. Sir JOHN HUTTON, who is an upholder of the Department, said he was obliged to come to the conclusion that the experiment was not one which should be entrusted to it. Sir J. B. MAPLE drew attention to the unfairness shown to the contractors who were put to trouble without any chance of success. On the other hand, Mr. JOHN BURNS made the astounding statement that from a workman's point of view it was a matter of vital importance that the Council should do the work itself, for the loss of life per 500,000*l.* worth of work done by the Council was smaller than the loss of life per 200,000*l.* worth of work done by contractors. As there is now a Workmen's Compensation Act in force statistics of the kind are less appalling than formerly, but the figures were enough to subdue opposition to the proposal, for a majority approved of the expenditure of 284,445*l.* in order to keep the Works Department going. To apply Mr. MICAWBER'S words, the probability is when the end of the amusement draws nigh we shall be very considerably astonished.

A MEETING was held at Marlborough House on Tuesday for the purpose of promoting a scheme to establish some permanent memorial to the late Sir J. E. MILLAIS, P.R.A. Owing to his recent accident, the Prince of WALES was, unfortunately, unable to preside, and the Duke of WESTMINSTER took the chair. A sub-committee, consisting of the Dean of ST. PAUL'S, Baron FERDINAND DE ROTHSCHILD, the Right Hon. CHARLES STUART-WORTLEY, M.P., Sir CHARLES TENNANT, Sir W. B. RICHMOND, K.C.B., Sir EDWARD J. POYNTER, P.R.A., Mr. JAMES KNOWLES, Mr. PETER REID, Mr. ALFRED WATERHOUSE, and Mr. WALTER W. OULESS, was formed to consider and report to the general committee the form which the memorial should take. Baron FERDINAND DE ROTHSCHILD consented to act as the treasurer, and Sir EDWARD J. POYNTER and Mr. PETER REID undertook the office of hon. secretaries. It was agreed to postpone an appeal for subscriptions until the form of the memorial should be decided. A vote of thanks was passed to the Prince of WALES for his offer to preside at the meeting, with a unanimous expression of regret at the cause of his Royal Highness's absence.

IN the charge to the clergy which was delivered on Tuesday, the Bishop of CHICHESTER recommended that great care should be taken that the glebes and other possessions of the Church are carefully set down in writing, and this safely kept. Much has been lost in times gone by from the want of such documents. Ignorance and encroachment have gone hand in hand in some places, and the Church is poorer to-day in consequence. Every parish should have its vestry book, and if in such book not only accounts but any event happening in the parish of real interest were recorded, there would be a gradually accumulating and true history of England in the vestries of our parish churches. The newspaper correspondent (and one appears to be found in every village) takes care to record all events of real interest, but all archæologists will admit it is an advantage to have entries of whatever relates to Church affairs, however remotely, entered in volumes which are trustworthy. Parish histories become more and more interesting as time runs on, and the Bishop of CHICHESTER'S advice is no less applicable to other dioceses.

BIDSTON COURT, a half-timber structure designed by Messrs. GRAYSON & OULD, and standing in grounds having an area of 31 acres, was offered for sale by auction in Liverpool on Monday. The most striking features of the exterior of the mansion are the twin-bays copied as closely as possible from those at Moreton Old Hall. Upon them is carved and painted in quaint and legible characters the inscription, "This house was built by ROBERT HUDSON and GERDA, his wife, Anno Dom. MDCCCXCI., these bay windows being copied from those at Old Moreton Hall in the hope that when they have perished these may remain." Upon the beams carrying the gables of the porch and great hall towards the court are the verses :—"When the trees are white with rime, And the ground is black and bare, Warmth and welcome ye shall find Underneath these gables faire. Charitie and jollitie Carve on every beam of wood, Mercie, truth, equalitie, Man's eternal brotherhood." Facing the whole length of the south front is a Dutch formal garden, the paths paved with white cobble stones, and the whole centring round an old Italian marble fountain. The fittings of the interior of the mansion are on a sumptuous scale befitting the character of the property. It is understood the property cost from 80,000*l.* to 90,000*l.* The bidding commenced with an offer of 10,000*l.*, and was increased to 25,000*l.*, but as no higher amount was to be obtained the property was withdrawn. The mansion, with about 7 acres of land, was offered as one lot, but the bidding was declared to be insufficient.

M. BUQUET, the architect for the new Hall of Assembly in the Chambre des Députés, is now busily engaged on the plans, but as yet they can be considered as only trial sketches. M. BUQUET has been studying all the available plans of the houses of parliament in various parts of the world. He is said to have come to the conclusion that a large number of them owe their form mainly to the diagram that VITRUVIUS put forth as representing the antique theatre. Among the buildings in which he could trace the influence of that plan are the ancient Hall of the Five Hundred, the senate chamber in the Luxembourg, the hall in the Palais Bourbon which is about to be abandoned, the two chambers for the Austrian Parliament, and, most remarkable of all, the new Reichstag hall in Berlin, which is found to be almost identical in plan with the Congress chamber at Versailles. M. BUQUET proposes to adopt an elliptical plan for the new building, but before deciding on the measurements he will visit the Parliament House at Buda Pesth, which has received much commendation. It is mysterious that M. BUQUET has taken no note of the Westminster chambers, although in them the most successful of parliamentary proceedings are held.

LAST year much interest was excited by the discovery at Delphi of the music which was used by the Greeks for two hymns to APOLLO. A similar discovery has been made in the Laurentian library at Florence. This is a fragment of VIRGIL'S "Æneid." The manuscript is apparently of the ninth century, and contains the notes from which the fragments were recited or chanted, for according to some authorities the declamation of the ancients was arranged with an art corresponding with what is seen in recitatives. M. COMBRIEU has reproduced the manuscript and has explained the system of notation with much acumen.

THE NEW PUBLIC OFFICES.

IN the House of Commons on Monday, the First Commissioner of Works announced that the Government had requested Mr. J. M. BRYDON to prepare plans and drawings for the new public offices on the Parliament Street site, and Mr. W. YOUNG to prepare plans and drawings for the new War Office on the Whitehall site. The plans when completed would be considered by the Government, and before orders were given to proceed with the buildings the drawings would be exhibited for the inspection of members. There can be no question about the competence of the two selected architects to undertake the important commissions they have had the good fortune to receive. If, however, there was less secrecy adopted in their selection there would be more satisfaction about the result, for it is impossible to say what circumstances determined the decision of the Government. It would be vain to deny that several architects have aspired to be entrusted with the new buildings, and they must be disappointed. But in architecture casualties of the kind are common, and a man is not fitted to follow the profession who is unable to endure them. Practice is to some extent a lottery, and one day or another every individual architect may hope to draw a big prize. All should endeavour to be as well able to turn it to good account as Mr. YOUNG and Mr. BRYDON. They have an onerous task before them, and for the sake of the profession in general we hope they will carry it out in the most successful way.

For it should be remembered that important official buildings like those proposed to be erected exercise influence over architecture for many years after their completion. Somerset House not only upheld the Italian style but set a fashion for "an easy-flowing foliage and an elegant imitation of such flowers and plants and other objects in nature as were best adapted to the purposes of architectural ornament." Who could think ill of any variety of Gothic when the Houses of Parliament were there to testify that our legislators could not discover another style so well adapted for the multiform duties imposed on the Lords and Commons? If it were not for peevishness of the lawyers and litigants who use the Law Courts, Gothic might still be supreme in England. The defects of the Home and Colonial Offices have had much to do with the preference for Queen Anne. If the classicism of the new offices can escape censure, it is reasonable to conclude that the style or styles adopted for them, however pronounced, will set the fashion in popular architecture. Stucco of a decorous drab colour might for a time obtain a preference over red brick, which, it may be remarked, is now becoming so glaring as to suggest its last days are approaching. Of all exaggerations those of colour are the most unpleasing, and some builders insist on having scarlets, which are subversive of the repose which red brick was diffusing through the land.

There is no fear that the new offices will offend the eyes of the judicious by any discordant scheme of colour, for it is stipulated that the exterior of the buildings must be constructed entirely of Portland stone. But the use of coloured materials in the manner which is now obtrusive enough is only one element in the fussiness which is taken to be a characteristic of architecture. It is well to have variety, but when we meet with surprises in every square yard, nay, sometimes in every square foot of frontage, it is difficult to resist a desire for relief if it were only as a monotonous plain surface. We appear to be fast approaching the vitality which WREN saw at Versailles, where "not an inch within but is crowded with little curiosities; works of filgrand and little knacks are in great vogue, but building certainly ought to have the attribute of eternal." If the new buildings in Whitehall and Westminster will serve as correctives to much of what now passes as advanced architecture, they will be worth the money expended on them, regardless of their use as offices.

The time is ripe for an effort which will recall the old glories of the art. The advance in draughtsmanship has caused it to be associated with the picturesque rather than with stability, and although buildings rarely collapse in England, the representations often excite doubts about the agency which keeps parts together that appear to be combined at random. But we cannot expect to have great works unless time is allowed to the architects to be satisfied with their designs. SCOTT, although he was practising in a style which was not familiar to himself or his assistants, was capable of producing a less unsatisfactory imitation of Italian than is seen at Whitehall if the pressure of officials had been less forcible. STREET was so worried by his sacrifice of portion after portion of his design to satisfy the First Commissioner of the time, it is a wonder the maimed remains retain so many excellent qualities. To the official mind the preparation of a design is a less important affair than the drawing up of a memorandum or a minute, and it is inconceivable why designs should not be produced with as much facility as documents. Legends about painters and sculptors continuing in a condition of mental distress because inspiration will not come when desired are accepted as credible, but that architects should also pine for forms to reveal themselves definitely seems as absurd as for a Government clerk to need a happy thought before he fills up a form. We hope the architects for the new offices will be allowed sufficient time to mature their ideas. It may be granted that accommodation is urgently needed, and economists will be dissatisfied if they see the sites for the buildings unoccupied. But allowance should likewise be made for the coyness of invention which is not always as spontaneous as one desires, and is not to be generated with the same ease as electricity. The conditions are so favourable for the production of excellent work, it will be difficult for the architects to come up to the anticipations of all who are competent to judge. The knowledge of that fact may spur Mr. BRYDON and Mr. YOUNG, but it may also be a restraint on their powers. They are expected to surpass all their former works, and that is not an easy task for any architect who always endeavours to be at his best. Let the authorities be careful not to make the task more onerous by meddling. The doctrine of non-interference is as applicable in dealing with artists as with foreign Governments, although it does not appear to be included among the rules and regulations of the Office of Works.

GERARD ON TASTE.

IN 1755 the Edinburgh Society for the Encouragement of Arts, Sciences, Manufactures and Agriculture offered a gold medal for the best essay on "Taste." None of the attempts submitted was considered worthy of the prize. The offer was repeated in 1756, when the Rev. ALEXANDER GERARD, D.D., Professor of Divinity in King's College, Aberdeen, sent in an essay, or rather part of a work, which he had completed on the subject, and the medal was awarded to him. Prize essays are not always prized by posterity, and although GERARD published his inquiry in its complete form, it has shared the fate of the majority of ordinary college exercises.

The book merits more consideration than it has received. If it has not created artists and amateurs, a similar powerlessness has marked more elaborate works of the class in all ages. We cannot be said to have arrived at success in our times, although more attention is given to the subject than in preceding periods. Newspapers in the remotest districts of most European countries would not now hesitate about announcing and applying principles of taste. On the basis of their temporary convictions, ancient and modern works would be judged without the least misgiving. It would seem as if the rules of good taste are so definite, they can be employed as readily and with as much certainty to determine qualities as a foot rule or a pair of scales can be used to measure size or weight. There is so great confidence on the subject prevailing, and everybody is so ready to pose as a legislator, it seems incredible to find an able writer like the late ALEXANDRE DUMAS the younger declining to lay down any rules on the subject, although it was well known that he bought and sold pictures with a success which dealers envied. He disclaimed all knowledge of laws, and the only explanation he could give of his competence was that he followed the guidance of his sentiments, his natural taste, and the experience which can be obtained by anyone who will use his eyes in a city like Paris.

DUMAS was a type of the most advanced class of latter-day amateurs. He enjoyed works of art, he could talk and write about them with eloquence and discernment. He had also the satisfaction of knowing that at the worst his pictures would realise the money he gave for them, and his enjoy-

ment was therefore obtained without more cost to himself than the ordinary interest on the sum expended. Yet he declared that, with all his success, "Je n'ai pas la prétention de faire une lois pour les autres." In other words, his pleasure arose from following his personal preferences, and not from obeying the dictates of theorists or the counsel of experts. It was open to ordinary men to imitate him. They might not make as much profit whenever they resolved to change their pictures, but at least they would have the satisfaction of exercising such powers as they possessed. Their works of art would be to some extent an expression of themselves.

The right to individuality which DUMAS claimed as an amateur he would naturally allow to artists. If "une loi" could not be made by so practised a writer for the guidance of men like himself, it would be still more absurd to attempt such a legislative feat for the benefit of artists. Why should BOULANGER, GÉRÔME, MILLET, COROT, MEISSONIER, have to succumb to an amateur's edicts? DUMAS for his own gratification preferred works in which the individuality of the artist was most strongly exhibited, and for the sake of the characteristic he was ready to condone departures from the precedents which had received academic sanction. So much latitude is one of the consequences of the numerous endeavours to produce works of art which will find a market, and the no less numerous endeavours to explain the points in which they are successful or deficient.

But in 1755 there was a belief in the existence of some beau-ideal which, if it could not be represented in stone or bronze, on canvas or paper, was at least capable of being suggested by words. There was accordingly peculiar fitness when the Aberdeen professor of divinity undertook the explanation. As truth was said to be single, it could not be opposed by truth, and to Dr. GERARD science, criticism, philosophy, were as applicable in questions relating to the arts as in those which related to theology. Processes resembling measuring and weighing if employed were supposed to determine difficulties. To use his own words, "Many of those qualities in objects from which the pleasures of taste result are capable of being measured with considerable accuracy," and he gives one instance to show how he would carry out the process :—

> The Grecian architecture excels in simplicity; this is unquestionably a source of pleasure. The Gothic has variety; this is likewise a source of pleasure. Which of them is most approvable? Of two sublime objects one exceeds the other in magnitude, but falls as much below it in simplicity. How shall we determine which is the most sublime? But this difficulty is not always insurmountable. It may happen, for instance, that one of the objects has more of approvable qualities, the other no more. The Grecian architecture has proportion, the Gothic is destitute of it; the addition of this quality plainly turns the balance in favour of the former. Thus, again, every work has its end and use: some qualities productive of pleasure may by their situation be subservient to this; other qualities very pleasing in themselves may by their position obstruct it.

There might be use occasionally in measuring the relations between solids and voids in a building, or light and shade in a picture; the proportions between the primary colours that produce "a neutralised bloom" can also be tested by those who are afraid to depend on their powers of vision, but what scale known to surveyors can be employed to bring simplicity and variety into conditions that are calculable? As long as the beau-ideal is indeterminate, it corresponds with the unsatisfied longing which appears to be inherent in the human mind; but as soon as precision is attempted we have a result which is neither fact nor fiction, and therefore misleading to those who are desirous to create.

GERARD was like many writers of the eighteenth century in his belief about the majesty of Classic buildings. It may be doubted whether his eyes rested on a single genuine example, and the representations which he could have employed were more or less fanciful. But on that account the beau-ideal of architecture was identified with a Classic building that was finer than any of those which were drawn as existing. He was unable to realise that there might be a second standard of the art, if not more. To GERARD the Gothic remains in Scotland were relics of a false system of divinity, that could only be produced in days when men were kept in ignorance, and education such as was imparted in his courses would therefore become fatal to Gothic as a style. He remarked in one place :—"The profusion of ornament bestowed on the parts, in Gothic structures, may please one who has not acquired enlargement of mind sufficient for conceiving at one view their relation to the whole, but no sooner is this acquired than he perceives superior elegance in the more simple symmetry and proportion of Grecian architecture." The Professor had no compunction about the condemnation of the college buildings where he taught and lived, which was involved in his words. That kind of heroic justice was common among the critics of his time. But what he could not have realised in 1756 was that the Gothic buildings of Scotland, which were supposed to be only pleasing to narrow minds, inspired WALTER SCOTT to undertake a revival which was equal to a new creation in literature, that SCOTT'S influence prevailed not only in English art and literature, but enkindled the romanticism of the French, and was almost as powerful in Germany. Let any one read what GOETHE says about the "Fair Maid of Perth," and it will be found that the qualities which he admired in the romance were (if unlike things can be compared) those which were condemned in Gothic buildings in the passage given above.

We must not be too hard on GERARD. If we consider the circumstances of the time, his book deserves to be admired as a remarkable effort. The Edinburgh Society realised the indifference to taste when the prize was offered for an essay on the subject. There were few books in existence to which GERARD could have recourse. HUME, in his "Treatise of Human Nature," had described the phenomena of association, which he had derived from THOMAS AQUINAS. GERARD was therefore able to say, "The principal source of grandeur in architecture is association, by which the columns suggest ideas of strength and durableness, and the whole structure introduces the ideas of the riches and magnificence of the owner." But he did not realise all that was to be accomplished about forty years afterwards with the aid of the theory of association by ALISON. REID was in 1756 one of the Aberdeen professors, but he had only published his essay on "Quantity." He had not then attempted to demonstrate that by the philosophy of Common Sense there was nothing really beautiful in the colour, form or exterior appearance of any object—there was only moral beauty, which had to be supplied by the spectator. HUTCHESON, who was not long dead, had by his theory of an internal or reflex sense of beauty maintained a similar conclusion. He was the English author who seems to have exercised most influence over GERARD, as we can see from many passages, and especially from one towards the close of the essay, where it is said :—"To those who are destitute of taste, general principles and rules, however just, will not supply the want of it; whenever they pretend to judge they will go wrong, not because the principles and rules are useless, but because they are incapable of applying them to the present case." Carried out to its full extent that conclusion would make all essays on taste almost useless, for if the man of taste is born, not made, it is waste of time to study principles which should be known intuitively.

The only book by a practical artist which fell in GERARD'S way was HOGARTH'S "Analysis of Beauty," and it shows a superiority to prejudice when we find the Professor so often quoting it. From the pages he was taught that the inexpressible greatness of the *Apollo Belvedere* arises from the uncommon length of the legs and thighs; that fitness was a principle of beauty; that the lowest utensil may be beautiful or ugly of its kind; that the curve was the line of beauty, &c. Occasionally we find passages in GERARD'S essay which suggest that, like HOGARTH, the Professor occasionally doubted whether an artist could as easily soar above the earth in his creations as theorists commonly assumed. For instance, he says :—

> It is possible to acquire so great refinement, especially when taste is accompanied with genius, that we conceive in idea a standard of higher excellence than was ever, in fact, produced; and, measuring the effects of art by this absolute and exalted form, we always miss some part of that immensity which we have figured out to ourselves. Leonardo da Vinci is said to have conceived so high a standard of perfection that, from despair of reaching it in the execution, he left many of his

features unfinished. When imagination is inflamed and elevated by the perfection exhibited to it, it goes on of its own accord to fancy completer effects than artists have found means actually to produce; by reason of some unpliableness in the materials employed, the execution seems always to fall short of our conception.

It is not the materials but the hand using them that fails whenever we are unable to realise our ideas. That expression alone would stamp GERARD as an amateur. But in the rest of the passage he gives one a notion that occasionally he was able to perceive that at its best man's work can be no more than approximation. One of the reasons which make the book interesting to a modern reader is that in it we see the contest between the student whose world was his library, and the professor who through his pupils was able to realise some of the shortcomings of life. He was forced to admit that men would run away from the beau-ideal if they saw anything novel:—"When genuine elegance in furniture or architecture has been long in fashion men sometimes grow weary of it, and imitate the Chinese, or revive the Gothic taste, merely for the pleasure they receive from what is unlike to those things which they have been accustomed to see." GERARD himself was not above yielding to the temptation. He also occasionally rebelled against a rigid correctness, for, as he said:—"To disapprove a transgression of a general law when the spirit is observed, and when the end is, perhaps, more effectually promoted, is not justness but servility and narrowness of taste. PARMEGIANO is said by good judges to owe the inexpressible greatness of manner in his pictures to the neglect of just proportion in some of the members of his figures." He was probably also disclosing a weakness which some readers would not fail to utilise when he said, "There is scarce any quality that recommends a person more strongly to our friendship than a fitness for gratifying our taste in some way or other." GERARD considered that taste was a sort of basis for all passions, with the exception of avarice. There is nothing like leather, said the old fable; there is nothing equal to taste, said Professor GERARD. But with all his belief in its efficacy, he did not dare to suggest that the temples in which his students were to officiate should be made to have less resemblance to barns. In the middle of the eighteenth century it required more courage than he possessed to advocate the employment of architecture as an auxiliary to religion.

In those days public opinion did not count for much. The multitude were expected to follow their leaders. GERARD could not imagine the possibility of a critic on architecture, sculpture and painting in every little town in Scotland where there was a newspaper, and of correspondents who would assert their claims to dispute anything favourable that might be said about Classic architecture or PARMEGIANO. When critics arose in England it was, as GOLDSMITH informs us, sufficient to say the artist would have done better if he had taken more pains and to introduce something about PIETRO PERUGINO. But that formula would have appeared revolutionary license to Professor GERARD. He would have no self-appointed critics. His arbiters of taste were to be carefully selected, and it would be a sort of heresy to fail in accepting their opinions. His words are:—

> Though general or universal approbation be assigned as the test of excellence, it really amounts to no more than the approbation of a very few. Multitudes are excluded from the right of suffrage, as being in one respect or another unfit to judge; the select few take the lead; what pleases their vigorous and improved taste ought to please all; whoever dissents ought to impute it solely to his own want of taste. An authority so absolute and uncontrollable had need to be clearly established.

STRATFORD PARISH CHURCH.

THE parish church, Stratford-on-Avon, was reopened on the 14th inst. by the Bishop of Bristol, after having undergone partial restoration. The church, apart from its Shakespearean associations, is most interesting. Portions of the present structure date from the time of the Norman Conquest, additions having been made in the thirteenth and fifteenth centuries. The church possesses some fine monuments, and is known as the Westminster Abbey of the Midlands.

Some years ago Mr. Bodley, A.R.A., prepared a scheme of restoration, part of which had been carried out when the work had to be stopped for want of funds, 6,000*l.* having up to that time been expended. Last autumn a public appeal was made for 5,000*l.* more to complete the work, and the work was resumed—to relay the floors of the nave and transepts, reconstruct the organ and provide new heating apparatus, and seating. The church has been closed for six months to carry out this work, and over 3,000*l.* has been expended upon it, but even now the task is uncompleted. A new vestry and a pulpit are wanted, and the nave requires to be seated with oak benches to match those in the aisles. A further sum of 2,000*l.* is needed, but as the committee are already considerably in debt, this latter portion of the work will have to be deferred. The reopening ceremony last week was attended by the Bishop of Bristol, who preached in the afternoon, taking as his text the words, "O, how amiable are Thy dwellings." His lordship said the word amiable, even in its personal application, might be applied to the fabric of a church, which spoke to them gently, tenderly, consolingly, and yet so firmly and so unmistakably. A church might be regarded as a voice in stone. In every stone of the fabric there seemed to be a rebuke to sin. How often, when one stepped into a quiet village church—to see, perhaps, whether the architecture was Norman or Early English—had one remained to receive such influences as these. The church in which they were assembled was to them a great inheritance and an immense responsibility—an inheritance not only of the beautiful fabric, but of the world-wide reputation that centred about that place, wherever civilisation was known and culture had reached. The church and the memory of him who once worshipped there spoke to their hearts and souls and consciences and told them of the great responsibility of that priceless inheritance. What would they who had to worship in great cities give to be able to approach their church through that avenue of lime trees, and to worship amid such peaceful surroundings. When one stepped out of a city church and stopped to dwell on some high and holy thought, it was at the risk of being run over. The world was always too ready to run over one at such times. The fabric of the church spoke to them in a voice which never jarred upon one whatever one's feelings might be. But that fabric, though it spoke to them with the voice of God, was the work of men's hands; still more did man's handiwork speak to them in Scripture. Who was worthy to stand before and interpret to himself the lesson of a great statue? In painting the skill of man appealed to them still more. What a revelation came to one when one sat down for a few moments before a great picture. But by far the greatest creation was the "maker," the man who made poetry or who made prose. In the early times of Greek art sculptors of the battles between the Centaurs and the human race made it clear that the Centaurs were so powerful because they used the simplest weapon—the weapon of nature. It seemed to him, as compared with the polished writers of the present day, the old writers had the greater power, because they used the natural weapons which were so simple. So Shakespeare was so natural and so strong that they almost forgot he was a supremely great poet. In thinking, how natural, how simple, how plain he seemed. That was a great lesson to all of them.

ARCHÆOLOGY OF THE PETERBOROUGH DISTRICT.

ON Thursday, the 14th inst., the fifty-fifth congress of the British Archæological Association commenced at Peterborough. Before the formal opening several of the visitors met at the cathedral, where Dean Ingram delivered an address on the history of the building.

Peterborough Cathedral.

The Dean traced the history of the first Saxon church, which was commenced in 656, on the site which, as nearly as possible, is now occupied by the south transept. He related the familiar legend of St. Chad in connection with the building of the church, which was destroyed by the Danes in 870. The second Saxon church was built about 970, and a wall was placed round it. Only within the last few days remains of this wall had been found under a portion of the eastern chapel, now being made secure. The Dean dwelt at some length on the legend of St. Oswald's arm, and said that for a long time this was the great relic of the church. In 1116 the whole church and monastery were destroyed by a fire that raged for fifteen days. The building of the present church, the choir of which was commenced in 1117, was completed in eighty-two years, and that perhaps accounted for the continuity of the whole design, Peterborough Cathedral being unique in this respect. The Dean drew special attention to the painted roof of the nave, which he said was no doubt expected by the monks in 1170, and was the oldest wooden roof in England. The west front must have been designed and built in the time

of five abbots, and none knew for certain who designed and who built it. Referring to the windows, the Dean said the whole were filled with stained-glass in the fourteenth century, but the only glass that remained after the brutal destruction of Cromwell's soldiers in 1643 were the two small lights in the eastern apse. Fortunately, added the Dean, there was no dynamite in those days, or they would not have had a cathedral now. The Dean then conducted the party round the cathedral. He pointed out the stone said to be erected by Godricus of Crowland over the grave of Abbot Hedda and his eighty-four slaughtered monks. Although Mr. Bloxam at a former meeting of the Association had sought to prove that the stone belonged to a period many years later, and was not a commemoration stone at all, yet he felt sure himself that it was the original stone, and this opinion was shared, he believed, by everyone whose opinion was considered anything at all.

The restoration of the great central tower was also alluded to, and the Dean observed that nearly 70,000*l.* had been spent upon the cathedral within the last 16 or 17 years. The west front came in for special attention, and before conducting the party up the scaffolding the Dean said :—"Very recently I was held up to scorn, ridicule and contempt of the world by a number of people who were totally ignorant of what they were writing about, and many of whom had never seen the cathedral. They imagined I was going to destroy the west front, but nothing was further removed from my mind than that idiotic notion." A number of the visitors (including the Bishop of Ely and half a dozen ladies) mounted the wooden scaffolding and were brought face to face with the work that has been carried out. The Dean explained that every stone was, where possible, replaced in its original position. Altogether 2,006 stones were taken down, and it was only found necessary to renew 170, most of which were hidden from view.

Afterwards the visitors were received at a garden party in the grounds of the bishop's palace.

The general meeting was held in the Assembly Rooms in the evening. Several water-colour drawings and other views of churches and other buildings of the district were exhibited, as well as some of the objects which were evidence of Roman occupation. The Bishop of Peterborough, in his address, said he recognised that as an antiquarian his presence was something of an anomaly, but in his official capacity he had pleasure in welcoming the British Archæological Society to the cathedral city of Peterborough. In the matter of population and industrial importance, Peterborough was below the class of town which the congress usually made its venue, but the locality had much of archæological interest to recommend it. That being the case, he wished the delegates a hearty welcome, and a pleasant and a profitable sojourn among the people of Peterborough. They not only desired that that particular congress might in some way start a new epoch in the life of the Association ; not merely be the result of sending each member a step forward in the science of his choice ; not only to take away from the locality a fund of knowledge and archæological mental pabulum which in the coming winter might be reduced to valuable pamphlets, treatises and reports ; not only leave behind them at Peterborough memories of their eight days' stay and pleasant friendships, but that there might remain some practical efflorescence, some imperishable memory. The Lord President proceeded to deal with the programme of the congress, and, alluding to the visit to Fotheringhay Castle, said that place possessed a historic interest a parallel of which would hardly be found throughout the length and breadth of the land. He characterised Fotheringhay Church as "a splendid structure melting slowly away," and urged the paramount necessity of rescuing that beautiful fabric from impending ruin, and maintaining it as a suitable English memorial to the memory of Mary Queen of Scots. Were that congress to result in a development such as he had indicated it would not have been held in vain. The character of the nation's life was changed by work such as that undertaken by the Society. The young country had no past from which to draw the lessons of to-day. She might be smarter, more go-ahead, quicker in her intentions, more pliable and self-adaptable ; but America, for example, would give a large slice of her national wealth for such a treasure-house of archæology as England possessed. America knew what an influence this was in making character and forming men. She knew the value of that power of retrospect, and that a nation's greatness in the past was a large factor in her present power and future strength. Bishops owed another debt of gratitude to the Society for its work in the formation of English character and the steadying of English lives. They all knew the value of the study of archæology in the rectories and vicarages of the clergy. When golf, bicycles, tennis and croquet made such demands upon men's time, it seemed especially desirable that such higher pursuits—which were more suitable, perhaps, to the employment of the spare time of the members of the learned professions—as the great science of archæology should be commended both by example and precept to the attention of the country clergy. His lordship devoted a considerable portion of his address to the Little Gidding community and the work of Nicholas Ferrar, who was visited by King Charles after his defeat at Naseby, and this fact, no doubt, caused the ruthless destruction by Cromwell's soldiers. The latter portion of his lordship's address was devoted to the cathedral, and he prefaced what he said by the remark that they would excuse him, as the twenty-eighth bishop and successor of forty-five abbots, if he desired to fix their interest upon it. In retelling the story of its vicissitudes, he incidentally mentioned the work of his hero-worshipping uncle, Charles Kingsley, who little knew at the time he justified by his novel the sacking of the abbey by Hereward, that his nephew was to succeed to the See. A passing allusion was made to the west front controversy. If, to use a vulgar phrase, "seeing is believing," then their presence, said the Bishop, would give wider force than anything else could do to induce the public to believe that the architect and the Dean and Chapter acted rightly. They had preserved one of the most perfect specimens of Gothic art.

Dr. Walker read a paper dealing with the Roman occupation of the district, showing that Castor and Peterborough formed an important centre as shown by the remains that had been frequently discovered.

Mr. Romily Allen (treasurer) proposed a hearty vote of thanks to Dr. Walker for his paper and to the Bishop for presiding.

Among papers promised to be read during the congress are the following :—"Lathom Hospital and its Early Statutes," by Lord Melville ; "The History of Ramsey Abbey as Illustrated by the MSS. in the British Museum," by Dr. W. de Gray Birch, F.S.A. ; "Yaxley and Fotheringhay Churches," by Mr. H. M. Townsend ; "The Gentlemen's Society in Connection with Peterborough," by Mr. C. Dack, local hon. sec. ; "Castor Church," by Mr. J. C. Traylen ; "The Roman and Saxon Occupation of Peterborough," by Dr. Walker ; "Maxey Church and Parish," by Rev. W. D. Sweeting, M.A. ; "Northborough Church and the Cromwells," by the Rev. H. J. D. Astley, M.A. ; "The Crosses of Fletton and Helpston," by Mr. C. Lynam, F.S.A. ; "Bury Church, Hunts," by Mr. J. A. Poulter ; "Crowland and the Legend of St. Guthlac," by Miss Edith Bradley ; "Notes on the Fenlands," by Prof. T. McKenny Hughes ; "The Commercial Importance of Peterborough in pre-Roman Times," by Dr. Phene, F.S.A. Papers also will be contributed by Mr. G. Patrick, A.R.I.B.A., hon. sec. ; Mr. J. W. Bodger, local hon. sec., and others.

THE ARCHITECTS AND CORPORATION OF PLYMOUTH.

A FEW months ago the special works committee of the Plymouth Town Council considered it would be wise to make arrangements in order that the buildings which were to be erected in connection with the Tavistock Road improvement should not possess the commonplace character which characterises provincial towns when the building owners are left unrestricted liberty. Accordingly, they offered some modest premiums to the local architects. But whether from an oversight or from want of acquaintance with the usual procedure, the conditions were not considered satisfactory to architects or advantageous to the town. The architects in a friendly spirit appointed a few of their representatives to wait on the committee in order to explain their objections. The interview was followed by the subjoined correspondence :—

I

Plymouth : May 14, 1898.

Mr. J. H. Ellis, town clerk, Plymouth.

Dear Sir,—In reply to yours of the 3rd inst, we beg to thank you for the privilege granted us of laying before you personally through our representatives our objections to the terms of the above competition, and for your kind consent to bring these matters and our reasons for objecting thereto before the special works committee.

We also beg to thank the special works committee for receiving our objections, giving them careful consideration and modifying the terms of the competition on certain points ; but we regret that the main points of our objections have not met with a more favourable reception, and we desire to appeal to the committee for a further reconsideration of the conditions of the competition, and ask to be allowed to offer the following suggestions for amending the said conditions :—

1. That the competition shall be confined strictly to the designs of elevations only, drawn to a scale of 16 feet to the inch, with enlarged drawings of all blocks varying from each other in general character, drawn to a scale of 4 feet to the inch.

2. That an architect, who shall be nominated by the Royal Institute of British Architects, shall be appointed as assessor, and that the terms and conditions of the instructions to architects shall be submitted to him for his advice and approval thereon.

3. That all the designs sent in shall be submitted to the assessor, and that he shall select from these designs three which are in his opinion the best, and award three premiums of the value of 70*l.*, 60*l.* and 50*l.* respectively to those placed by him first, second and third in order of merit.

4. That all the designs, including the premiated drawings, after having been exhibited to the public for seven days, shall be returned to their respective owners, and a copy of the design selected for carrying out shall be at once supplied to the borough surveyor, and retained by him for reference.

5. That the architect who is the author of the first premiated design shall provide working and detail drawings, together with full-size detail drawings of all moulded and enriched work to the purchaser (or his professional adviser) of any one or more of the sites, and that he shall have power to enforce the carrying out of the design on the lines approved by the committee, and for such services he shall be paid a fee of seven guineas on each site by the purchaser thereof.

6. We object strongly to supply designs for plans, as we hold that it is desirable in the interests of the town, as well as in the interests of our profession, to give freedom to the purchasers of sites to carry out their own requirements in planning, and that they should be restricted only to number and heights of floors, to lines of front and back boundaries and designs of elevations.

Trusting that our suggestions may have the favourable consideration of the committee, and be received in the same spirit with which they are offered.

(Signed)

II.

Town Clerk's Office, Plymouth: May 17, 1898.

Dear Sir,—I beg to acknowledge the receipt of your letter of the 14th instant, and the accompanying letter signed by architects practising in the borough, which I submitted to the special works committee at its meeting yesterday.

I am directed to inquire whether, provided the committee are prepared to consider the suggestions submitted by the architects, they would be prepared to waive their requirement in relation to the appointment of a professional assessor.

I may add that I have instructions to convene a special meeting of the committee as soon as I receive your reply to this inquiry. J. H. Ellis.

B. Priestley Shires, Esq.

III.

May 20, 1898.

J. H. Ellis, Esq.

Dear Sir,—In reply to yours of May 17, the question of a professional assessor being appointed on the above competition has been fully discussed by the architects of Plymouth, and they are unanimous in declining to enter the competition unless this condition is granted.—p.p. the Architects of Plymouth,

B. Priestley Shires.

IV.

Town Clerk's Office, Plymouth: June 7, 1898.

Dear Sir,—Referring to previous correspondence hereon, and particularly to the architects' letter of the 14th ult., I beg to say that the special works committee has decided to recommend the Council to meet the objections and suggestions put forward by you and your brother architects in the following manner, viz.:—

They will agree to the appointment of a professional assessor, provided the premiated plans become the property of the Corporation.

The premium to the successful competitor to be 250*l.*

The committee regret their inability to dispense with any of the drawings mentioned in paragraph 4 of the instructions to competing architects, and, in this connection, I would reiterate the statement contained in my letter of the 3rd ult., to the effect that the committee propose only to exhibit publicly the elevations of the whole façade, so that no opportunity will be given to unscrupulous persons to take advantage of the labour of competitors.

The committee cannot agree to the fee of seven guineas on each site being paid to the successful architect by the purchaser thereof, as suggested in paragraph (5) of the letter of the 14th ult., and the fee of 250*l.* must be regarded as inclusive.

The committee has also decided to prescribe the following condition, viz. that competitors are to submit designs of premises which will produce a rental of about 100*l.* per annum, with the exception of the two end sites, which are to be specially treated.

I shall be glad to know prior to the meeting of the Council on Monday next whether the architects will be prepared to compete under the altered conditions of competition.

J. H. Ellis.

Mr. B. Priestley Shires.

V.

June 11, 1898.

Mr. J. H. Ellis, Town Clerk, Plymouth.

Dear Sir,—I beg to acknowledge receipt of your letter of the 7th inst., which I duly laid before the architects of Plymouth at their meeting yesterday afternoon.

I am desired to say that your letter of May 17 led us to believe that our objections to the terms of the competition (apart from the appointment of an assessor) would receive the favourable consideration of the special works committee. We are very much disappointed to learn that the only concessions are the appointment of an assessor and the increase of the premium. We are unanimously agreed that our objections to the terms of the competition are reasonable and are of considerable importance to us professionally, and we ask the committee to reconsider and adopt at least the general principle underlying the suggestion set forth in our letter of the 14th ult.—p.p. the Architects of Plymouth,

B. Priestley Shires.

It cannot be said there is anything unreasonable in the requirements of the architects. The buildings, we understand, are likely to cost about 50,000*l.*, on which the usual fees would be 2,500*l.* To accept instead a fee of one-tenth the amount—for that would be the practical result of the Town Council's proposition—would be not only fatal to the architects of Plymouth, but it would be detrimental to the interests of the profession throughout the empire. For if a fraction of the normal fees will be sufficiently remunerative in one case, they must be no less adequate in all others. There is also the danger that the premiated design would be copied or imitated by incompetent hands, and the laudable intention of the Town Council would be frustrated. By their departures from the original scheme the Council acknowledge they are not infallible, and without any loss of dignity or reputation they can concede all that is required by the architects, who cannot be indifferent to the interests of Plymouth. The Council, however, appear to think they must uphold a character for firmness. As they do not expect to be able to persuade the architects to adopt an irrational course, they have resolved to open the competition to the whole of the architects of the country upon the original conditions, which were briefly as follows:—1. One premium of 150*l.* for best design for twenty-eight shops and dwelling-houses, to be adjudged by the special works committee and not by a professional assessor. 2. The following drawings will be required:—

a. A block-plan, showing the whole of the buildings (twenty-eight shops and dwelling-houses), with the position of the drains and the extent of open space attached to each building.

b. Complete plans of each floor of the buildings.

c. Sections of the buildings.

d. Complete elevations of the whole façade, with enlarged details throughout.

The committee may be able to attract designs from gentlemen who have received their education in the School of Architecture at South Kensington, but no architect who is competent and possesses a character which is worth upholding is likely to be tempted to gratify the Plymouth Town Council.

THE LEIGHTON HOUSE.

It will be a sad and strange experience for many Londoners when they pass into "The Leighton House," as it is now called, to miss the kindly host who did the honours of it so well, and the stream of guests he used to welcome so cordially on those Sunday at homes in the early months of the year while his Academy works were being planned and carried through with such loving completeness. The opportunity is given two days in the week to those who apply for tickets to Mrs. Russell Barrington, the hon. secretary of the committee who have got together the drawings and studies which now hang on the walls and remind us of the great canvases which year after year were the pictures of their year, and of the infinite care which their painter devoted to them. The studies are in some respects even more interesting than the pictures themselves, and "Leighton House" will be a museum for the Londoner generally, but especially for the artist and the art student.

The house itself, says the *Daily News*, was for its owner as much a study and a labour of love as any of the works conceived and slowly built up under its roof. As you pass into the

inner hall, the bronzed cast of Mr. Brock's fine portrait bust is the first personal relic which meets the vision. It stands where the painter so often stood to meet his friends, and at its base is a wreath of bay leaves, the Daphne which he loved so to introduce into his picture, and which he drew with such finesse and accomplishment. Left of you is the Arab Hall, of which Leighton was so fond and proud. As you left the studio above, he would always beg of you to pass into it on your way to the hall. He and his friend Mr. Purdon Clark were one autumn travelling in the East, and arrived at some town where a mosque had just been pulled down, and all its appurtenances, including its tiles, were being dispersed. The chance was a great one for an artist, and especially for an artist who was also a colourist. Leighton bought largely—the carriage home was more trouble than the actual purchase—and the Arab Hall was the outcome of that special journey to the East. Across the darkened vestibule you see the domed hall, with its studied and effective lighting, its cool splashing fountain, its windows jewelled with old Damascus glass, its Cairene woodwork, old too, and of exceptional beauty, and its tiles of rich and passionate colour. The Moorish capitals of the columns were carved in polished marble by his friend Boehm, the frieze that runs between them was designed by Walter Crane, the Arabic characters in the architrave over the approach were once the salutation that met the worshipper as he entered the old mosque. It is a building to study and to linger in, and perhaps its greatest triumph as a piece of design and architecture is that it impresses you less in detail than in its harmonious completeness.

As one passes up the spacious staircase with its ebony balustrade, one follows the master from room to room. "Hic illius arma, hic currus fuit." On the wall is his copy of one of the Sistine frescoes. As you pass into the "Silk Room" you come upon studies and photographs of studies which serve to delight and to instruct. Here, on a screen, is a drawing of the little town of Cervara, signed "F. L. 1856." Leighton was a slim, long-haired young man when he visited Cervara first, he and a number of Roman art students halting there half-way on a picnic excursion. During the halt a beehive was accidentally overthrown; the bees, disturbed and infuriated, settled on the donkeys, and stung mercilessly one particular young animal that, unlike the others, had not "broken from its harness on that first assault." An older artist of the party has years afterwards tolds us how he saw a young man with wavy hair cover his face and draw gloves over his hands, and so protected come to the rescue of the poor tortured brute. That was the first introduction of Professor Costa to Leighton, and the commencement of a friendship that lasted through their lives. Cervara is a delicately pencilled little drawing, and the date is 1856. Of earlier date is the head of the boy "Vincenzo"—the prettiest and wickedest boy in Rome, Leighton used to say of this favourite model with the art students of 1854. Here, again, is a head of Dante, given by Canon Rawnsley, and dated 1853, and two landscapes of the Brescian Hills from Verona. In the ante-room on screens are pencil studies of flowers, mulberries, thistles, hollies—all showing that finesse of draughtsmanship in which he had few rivals. Most of these drawings are of Italian subjects, such as the Palazzo Rezzonico in Venice, where his friend Robert Browning was to end his days. How careful he was in his work, what a gift he had for taking additional pains, we see here again and again as we come on studies for well-known pictures, the figure first in the nude and then draped — he never spared his trouble. As we have said, the interest of this collection is for the student and for the artist more than for the general public. The visit is an education as well as an interest. And then Leighton too had in his nature a dash of satire. That his tremulous sense of beauty was not inconsistent with a gift of humour even exercised at his own expense may be seen in a caricature executed in his early Roman days, where he is represented receiving his artist friends, evidently at some fancy ball got up by the students. Here he stands, no slim youth, but a podgy citizen ill at ease in his Florentine hose, terminated by boots with spurs, while the procession mounts the stairs, a delicately featured poet, a Palmer, a Knight Templar, a sort of shoddy Brian de Bois Guilbert, and serving men sneering covertly or laughing outright. There is caricature in the attitudes, in the very legs of the figures as they mount the stairs. How glad one would be if Thackeray could have given us some account of this artists' ball, of the days when he and Leighton were young together.

As the Arab Hall was an adjunct to the house, so but a few years before its owner's death the top light, or glass studio, became for the painter a necessity. In this room, which was a workroom, and not always opened on his "At Home" days, are now shown some of the most interesting studies in the whole collection. These are copies which young Leighton made from Memmi's frescoes in the Spanish Chapel of Ste Marie Novella, when he was staying at Florence in 1853. Here we may see Taddeo Gaddi in white and gold cap; Giotto, gold and sea green; Cimabue, gold flowers on white ground. The criticism on these copies in the admirably written preface to the catalogue should be read carefully. It may be said generally of the drawings here exhibited that with those who only knew Leighton from his finished works they will increase an already splendid reputation; for even the slightest of these works exhibits that incommunicable gift of style which is the hall mark of genius, and only belongs to the great artist of all schools and all periods.

"HINGED" MASONRY ARCHES.

A PAPER was lately read before the American Society of Civil Engineers by Mr. David A. Molitor, in which he explained the advantages of masonry arches over iron and steel bridges, and presented a mathematical analysis of strains and loading in a three-hinged arch from which he calculated the deformation and determined the thickness of masonry. Mr. Molitor illustrated his methods by a practical design and estimate for a three-hinged concrete arch of 236·23-feet span, 46·57 feet wide, proportioned to carry a 44,000 lbs. electric motor car, besides a uniformly distrtributed live load of 82 lbs. per square foot. The allowed working strains are 568·8 lbs. compression and 28·4 lbs. tension per square inch on concrete composed of one part Portland cement, two parts sand and three parts crushed limestone. He gave detail tables of loads, strains and dimensions, and of quantities in the finished structure, which he assumed would cost about 96,000 dols. The purpose of the paper was to demonstrate that masonry arches may be constructed on any good foundation as accurately and simply as iron or steel structures, and sometimes more cheaply. He considered that the Austrian tests of 1890 to 1895 and the recent construction of a few long span three-hinged masonry and concrete arches inaugurate a new era in masonry bridge construction. According to Mr. Molitor all the harassing features of fixed masonry arches are overcome by the introduction of hinges at the crown and abutments, and by basing the design on the theory of elasticity, and that it is practicable to strain the material one-sixth of the ultimate strength of test samples.

The idea of crown and abutment hinges was introduced by Koepke, of Dresden, in 1880. Leibbrand, of Stuttgart, substituted sheet-lead for the open joints in 1885 and cast-iron hinge bearings in 1893. In 1880 Koepke built a sandstone arch in Saxony with 42·64 feet span and 9·84 feet rise, and a maximum thickness of arch-ring of 1·97 feet. The hinges consisted of a convex surface of sandstone, with a radius of 3·2 feet rolling in a concave surface, with a radius 3 6 feet. In 1885 Liebbrand built a sandstone bridge over the Enz river, near Hoefen, Germany, with a span of 91·86 feet, a rise of 9·19 feet and hinge-like joints of sheet-lead. In 1883 the same engineer built a concrete arch over the Danube river, near Munderkingen, Wurtemberg, which had a span of 164 feet, rise 16·4 feet and thickness 4·59 feet. This arch had three steel hinges and was made of concrete proportioned 1 to 2½ to 5. In 1893 Braun built a concrete bridge over the Danube, near Rechtenstein, Wurtemberg, with 75·45 feet span, 8 feet rise and 2·95 feet thickness. Lead strips were inserted at the crown and abutment joints. The concrete was made 1 part cement, 2½ parts sand, 5 parts gravel and ½ part quarry stone. In 1895 Butticaz built the Coulonvrenière Bridge over the Rhone at Geneva. This bridge has two spans of 131·24 feet, one of 45·92 feet and one of 39·36 feet, and is made of concrete with lead joints. In 1896 Leibbrand built a bridge over the Danube near Inzighofen, Wurtemberg, with a span of 141·08 feet, rise 14·62 feet and maximum thickness 3·6 feet. It had cast-iron hinge joints at crown and abutments, and was made of concrete, 1 part cement, 2½ sand, 4 crushed limestone and ½ limestone screenings. These bridges are stated to have given excellent satisfaction, and to have developed no cracks, although some were founded on piles or clay.

We are Informed that Mr. R. S. Henshaw, who has for many years filled the office of secretary to the "Institute of Builders" and the "Central Association of Master Builders of London," has found it necessary to resign those positions in order that he may devote himself entirely to the increasing business of the "Builders' Accident Insurance, Limited." Mr. Thomas Costigan has been appointed to the joint office of secretary to the "Central Association of Master Builders" and the "Institute of Builders."

Upon an Examination of the bells that are rung on the Royal birthdays in the Curfew Tower of Windsor Castle—one of which, the big tenor, suddenly fell during a recent celebration—it was found that the fifth bell was cracked. This weighs about fourteen hundredweight, and has been pealed at intervals for over a century and a half. It is composed of tin and copper and was cast in 1745.

NOTES AND COMMENTS.

IN the volume of the "National Biography" which was published a few days ago there is an article on the late GEORGE EDMUND STREET, R.A., from the pen of Mr. PAUL WATERHOUSE. The most important events of the architect's life are skilfully compressed in a few columns. His father was a solicitor, a descendant of a Worcestershire family that produced Sir THOMAS STREET, one of the judges who tried the Rye House conspirators. GEORGE STREET was also intended to follow the law, but a few months' experience of his father's office convinced him of his unfitness for the profession. His merits as an architect are analysed by Mr. WATERHOUSE in the following passage:—"Though never exhibiting any animosity towards the practice of Classic architecture, STREET had always looked upon Gothic work as his mission, and was consistently true to the style of his choice. In his earlier career he had leanings towards an Italian type of the style, and the special study which bore literary fruit in his 'Brick and Marble Architecture' was turned to practical account in the church of St. James the Less, Westminster. His later and more characteristic work was, however, based on English, or occasionally, as at St. Philip and St. James's, Oxford, on French, models of the thirteenth century; and although his work as a restorer led him more than once to practise in the methods of the late English Gothic or Perpendicular manner, this style was hardly ever adopted by him in original design. STREET was no slavish imitator; he gave full play to his inventive faculties, and his special invention of the broad nave with suppressed aisles, a device for accommodating large congregations, is well exemplified in the church of All Saints, Clifton. One of STREET's favourite designs was that of Kingstone Church, Dorset, carried out for Lord ELDON. It is a cruciform building with an apse, central tower and narthex built throughout of Purbeck stone with shafts of Purbeck marble, all from quarries on the estate. The mouldings are rich, and, owing to the character of the material, the building has a model-like perfection and neatness which age will probably improve. The American churches at Paris and Rome, and those for the English community at Rome, Vevay, Genoa, Lausanne and Mürren are also notable examples of STREET's work. It was in the parish church, large or small, that his genius was realised to best effect."

MR. FREDERIC HARRISON, who was chairman of the improvements committee of the London County Council in 1892, when there was a scheme for a new street from Holborn to the Strand, has written to the *Times* about the latest scheme for the same improvement, which he describes as bolder, larger and less costly than his own. Mr. HARRISON says "the new street will make it absolutely imperative to widen Waterloo Bridge and its approaches. And this problem should at once be attacked." But he makes a more remarkable suggestion when he proposes that Somerset House should be converted into a County Council Hall, as it is spacious, central and imposing. According to Mr. HARRISON, "There is no reason why wills, stamps, audit and the like should continue to monopolise the finest palace of Old London. It should belong to London and be devoted to London. The vast area to be cleared by the new scheme will offer ample sites whereon modern and commodious rooms might be erected for the miscellaneous departments which are scattered about Sir WILLIAM CHAMBERS's grand palace." We have no wish to say a word against a block of buildings which has become almost as much identified with London as St. Paul's. Mr. FERGUSSON has descanted on the shortcomings of a work which, according to him, proves that the designer "had evidently no grasp of mind or inventive faculty and little knowledge of the principles of art." It is very doubtful, however, whether Somerset House could be transformed into such a building as the County Council require. At present complaints are continually heard from the official occupants, and many of them would gladly fall in with Mr. HARRISON'S or any other scheme which would allow of their emigration. If the County Council wish to have a hall worthy of the Metropolis they can easily obtain a site opposite Somerset House, and they will be able to demonstrate that the rulers of London have quite as good taste as GEORGE III., and that as able an architect is to be found in our time as the clever sailor who was His Majesty's drawing-master. It is sad to see Mr. HARRISON incapable of rising to the necessities of the case, and afraid to do more than recommend a policy of vamping in respect of architecture. Age has no more pity on him than on other ardent reformers.

THE Historical Manuscripts Commission cannot be considered as neglecting its duties, and there are few papers of any value in private collections which are not well known to experts. The proposal to give the County Councils about to be created in Ireland authority to recommend the editing, translating, printing or publishing of any historical manuscript relating to the counties is not therefore of much practical value. It is true, as was said in the House of Commons some nights ago, that a series of memoirs in connection with the Ordnance Survey was at one time contemplated, of which only one volume was published. It related to the county of Londonderry. But the memoirs were not intended to be altogether historical. They were also to deal with the geology and natural history, the statistics and social condition of the various counties. The part relating to geology in the volume that was issued from the Ordnance Office afterwards appeared as a treatise on the science. If volumes could be compiled of the same class they might be useful. But there is already too much of what is called history accessible in Ireland, whilst it is difficult to obtain information which a business man can turn to account. No doubt the Celts have always a weakness for the past, for they can indulge their imagination in connection with it, but that sort of enjoyment has to be dearly paid for in a time when competition rules.

EVERY visitor to the Paris Exhibition of 1900 will, of course, expect to see the Gobelins worthily represented. The factory of Sèvres will also be expected to uphold its reputation. But while there are many rivals to the Government potteries of France, the tapestry-weavers of the Gobelins stand alone in their glory. The failure of the Windsor tapestry works, in spite of the exalted patronage bestowed on them, suggests the difficulty of upholding the production of woven pictures without the aid of a liberal subvention. It is well known that at the Gobelins there are several works in hand which will display the competence of the artists to deal with various styles of subject. M. J. P. LAURENS has prepared the cartoons for an immense piece which will represent a Mediæval tournament. That will be serious if not tragic in aspect. As a contrast will be a delightful panel after M. MAURICE LELOIR, called *The Romance in the Seventeenth Century*. M. ROCHEGROSSE, who takes his subjects from ancient history, has prepared the design of a suggestive work, *France as a Coloniser*. M. MAIGNAN will have an allegory derived from OVID's "Metamorphoses." The late M. GUSTAVE MOREAU was a mystical painter, somewhat allied to the English pre-Raphaelites, but he attempted one design for tapestry which is now being reproduced. It offers great difficulties to the weavers. M. GEORGES CLAUDE will have two pieces prepared from his designs. One will represent a *Civil Marriage in 1792*; the other a scene from VOLTAIRE'S "Zaïre" as performed at the Comédie Française, which is intended for the Maison Molière.

THE Sala Regia is one of the most pleasing parts of the Vatican. It was erected from the designs of SAN GALLO in the pontificate of PAUL III. Among the artists employed on the decoration were PIERINO DEL VAGA, DANIEL VOLTERRA, GIORGIO VASARI, SOMMACHINI, TADDEO ZUCCHARI, SALVIATI and SERMONETA. The ceiling is especially rich, as gilded, stucco and painting are combined to make it attractive. The walls are painted in fresco, and among the subjects represented are *The Interview between Pope Alexander II. and the Emperor Frederick I., The Battle of Lepanto, The Return of Gregory XI. from the Exile of Avignon, Gregory VII. and Henry IV.*, &c. The Sala Regia is about to be restored under the direction of the architect to the Vatican, Signor VESPIGNANI, who will be aided by Professor SEITZ and other artists.

CATHEDRAL SERIES.—PETERBOROUGH: TRIFORIUM.

INGLIS MEMORIAL HALL, EDZELL, N.B.

THIS handsome building, erected by Colonel Inglis, of Craigendowie, Reigate, and Adam's Court, London, to commemorate the life and labours of his father (for many years minister in Edzell), has now been handed over to the Parish Council of Edzell for the benefit of the residents in that popular health resort. Our plates show the appearance of the building, in the design of which it is evident the architects have been influenced by the historical buildings existing in the neighbourhood, which is fortunate in possessing specimens of ancient architecture of quite uncommon interest. There are no less than three Druidical temples in the parish. The old castles of the Lindsays, Edzell, Balbegno, and Invermark, not to speak of Brechin, with its cathedral and round tower, make the district architecturally one of the richest anywhere from an antiquarian point of view. The modern building we illustrate was the subject of a rather notable competition which took place about two years ago, and which was won by Messrs. Ower, of Dundee, out of a very large number of competitors—the adjudication being by London experts.

The hall owes its effect to its proportions and harmonious lines rather than to minute detail, though both carving and mosaics have been used where ornament was specially called for, at the main entrance door and elsewhere.

Granite shafts and Venetian enamel mosaic have been used with beautiful effect in the porch, over which appears the inscription in mosaic "Inglis Memorial Hall," in letters of the colour of old ivory, against a stone-coloured ground having a faintly relieved scroll of Scotch thistles on it. Over this rises the clock tower, and at the same level as the clock faces, a view-chamber with four openings commands the most extensive range in the district short of climbing the Grampians. The style used is Scotch of the sixteenth century.

The interior of the building is both useful and beautiful. Colonel Inglis has provided in it a library and reading-room, council chamber for the use of the parish council, one large hall for public meetings, and one smaller which can be used either separately or combined with the main hall. A complete scheme of cloak-rooms, kitchen, sculleries, with storerooms, &c., accompanies the halls.

The library, which Colonel Inglis wishes specially to connect with the Jubilee (Diamond) of Her Most Gracious Majesty, has been finished and fitted up in a most elaborate fashion, with all the improvements in use for the proper distribution and reception of the books, which already number over 5,000 volumes (the gift of Colonel Inglis). The windows of this room are filled with stained-glass, in which appear quaint Scotch proverbs bearing on life and conduct, the selection being Colonel Inglis's own. An iron staircase from the library floor gives access to the upper part of the bookcases, as well as to a workroom for binding and cataloguing on the first floor, on which is the caretaker's house, entrance to music gallery, and staircase to view-chamber in tower.

The works have been executed in the most substantial and artistic manner by the following contractors:—Messrs. J. Ford & Son, Montrose, masonwork; Messrs. J. Black & Son, Brechin, joinerwork and library fittings; Mr. J. Scott, Brechin, slaterwork; Mr. D. McKay, Carnoustie, plumberwork; Messrs. Thomson Brothers, Brechin and Edzell, plasterwork; Messrs. Mackenzie & Moncur, Edinburgh, heating; Messrs. Milne, Edinburgh, gasfittings; Messrs. Alexander, brassfounders, Dundee, hall pendants; Messrs. Wooliscroft, of Hanley, floor and wall tiles and mosaics.

Messrs. Salviati, of Venice, Messrs. Meikle, of Glasgow, and Mr. Fox Maule Boyd, of Dundee, have respectively carried out the Venetian enamel mosaic, stained-glass and painter-work, to special designs by Mr. C. Ower, to that gentleman's great satisfaction.

Mr. Robert Scott, of Arbroath, has acted as clerk of works, with the architects' entire approval.

Messrs. Wright, of Aberdeen, supplied the granite, and Mr. Annandale, of the Den Nursery, laid out the grounds.

Messrs. Henry Southern & Co. furnished the books, binding and catalogue.

Messrs. C. & L. Ower, of Dundee, are the architects.

LANDSCAPE PAINTING.

THE natural world, chiefly in landscape, has become the favourite art of this century. This argues a wholesome taste. Of the old, conventional religious landscape we have but few recent examples. Each artist affects to go to nature because the public mind insists upon nothing less. Many, however, deceive themselves and their friends by shamming what they have not the resolution to pursue. Correggio, considering his time, took perhaps the greatest step in divesting landscape art of its previous stiffness and formalism. He attempts the freedom and grace of nature, particularly in his foregrounds. To Titian, however, landscape is most indebted. Although he never wholly freed himself from the old system, yet his landscapes as a whole are simple and broad in character, giving the general features of nature, though not its variety. That which, however, he rendered in foreground detail is given with perfect fidelity of form and colour. Grandeur and majesty were his chief aims. We are impressed, however, both by the general spirit of his views and by the excellence of detached parts. His *St. Jerome*, in the Brera Gallery at Milan, is a happy example of how far he could steep nature in his imagination, adhering to her truths but investing them with occult meaning. Landscape with him, however, is always an accessory. One of the most attractive views, from the extent and variety he introduces, is to be seen in his Dresden *Venus*. Nature in his hands always maintains its dignity. In his skies there is perhaps a somewhat artificial rendering of light, as if he sought to exaggerate effects by a species of twilight mystery. He never painted actual sunlight, but tried to give a luminous, serious effect in harmony with his subjects. Sometimes, as in his *St. Catherine* in the Pitti Palace, the clouds are hard and monstrous, rendering his distant hills of blue, in comparison, quite transparent. These effects were, however, before his style in this branch was fully formed. Later, particularly in his trees, he was unrivalled, both in truth of quality and outline. In general, his water is liquid and his earth dry, telling with solidity against his sky, while his light is subtly and equally diffused throughout his pictures. Tintoretto felt landscape and had a greater grasp of imagination, but with less ability in technical expression than Titian. The world can judge of an artist's power only by its results. It has neither time nor inclination to spend over the illegible. The artist, therefore, who slurs his work from impatience, or aims only at coarse effect like stage scenery, paying no attention to the purity and permanency of his materials must, like Tintoretto, reconcile himself either to be forgotten or overlooked by the public. There is no injustice in this, because genius has no authority to outlaw the vehicles of its thought. To be successful it must be considerate in all things. Salvator Rosa gives confused dreams of the natural world. Much that is false in quality or strained in sentiment, he mixes with occasional bits of truth, fresh and vigorous from nature. He had power and will, but lacked judgment and patience. He did much, however, to recall love for open healthful scenery, and the motive and execution of his landscapes have yet power to charm. In Claude we see more truthful results from inferior natural abilities. He had no invention or taste in composition. Consequently his landscapes in general are unpleasantly artificial, indeed, we may say little in thought. But in his direct studies from nature there are more breadth, space and atmosphere than in his paintings. Architecture, such as then was the fashion, was in him a passion. He built it upon his canvases after a cold and stately ideal of his own, which reminds one more of castles in the air than actual habitable mansions. In drawing and variety he was feeble, but in the great qualities of sky, earth and water he created an epoch in art. An uninjured Claude is a rare object. Almost every one of his pictures have been more or less skinned, to use an expressive term, by the carelessness of cleaners. Instead of their original luminosity, we have cold, dry surfaces, yet, even in their loss, so infinitely surpassing in quality the attempts of other artists as to still claim for Claude the first position as a painter of the grand elements of nature. A sea-view of Claude's in the Academy of St. Luke, at Rome, and one in the Dulwich Gallery, and a few others, most favourably present his rare merits. In depth and unity of colour, subtle gradation of light and shade, sparkling liquidity of water, solidity of stone and opacity of earth and transparency of atmosphere, they are unrivalled. The water of these pictures is natural in quality; it brings with it the refreshing breeze and musical ripple, and suggests those moments in which nature is most charming. His sun is not a glaring white spot, but shines, diffusing light equally through the picture; it borrows no external rays, but covers all things within its influence with a trembling, luminous atmosphere of its own. The vegetation of some of his trees is massed with great naturalness. When art is so much indebted to one man, it seems like sacrilege to notice his deficiencies; but they are necessary to be exhibited as warnings to other artists to strive after a complete whole, while, with people at large, Claude will be remembered only by his diligence and success in making us feel the power of art to transfer to canvas

those general features which most constitute our delight in the natural world.

None of the artists mentioned, not even Gainsborough, with all his power and love of nature, can be compared to Turner in knowledge of landscape. To England is the honour due of producing the most complete landscapist—one who has shown us the capability of art to make us feel the variety as well as grandeur of nature. Turner was to the landscape what Raphael was to the human figure; each embodied in his branch of art a certain grace of expression, whether in repose or movement, hitherto unequalled. Everything that either touched, lived; its vital functions were at once fully developed. As complete, however, as was the external expression of each, we feel that the former has but suggested what remains to be done in comparison with the latter, who, in his water-colours, has created a new era in art. Turner gave the physical truths of nature, on every scale, with a fidelity and variety which placed him far above preceding landscapists. Through his works nature talks to us; she smiles or frowns, incites to action or invites to repose, as may be her mind. To no artist is the lover of nature more indebted than to Turner, for he has established a standard of truth in art from which the world will not readily forgive departure. The universality of his genius in this respect is remarkable. Other landscapists have contented themselves with being distinguished in parts, but he aimed at the great whole. Nothing created that was endowed with beauty, from an Alp to a limpet, escaped his notice. His true field was nature; but in the works of man he could equally distinguish himself. Few artists had ever drawn architecture like Turner; witness his cathedral at Rouen in his "Rivers of France." Ships, too, were his delight; he revelled in ocean sublimity and mountain grandeur. His heart was no less open to the joy of the plains and the quiet of valleys. Whatever he undertook he touched lovingly; at times carelessly, it is true, and even wantonly, but always with power and meaning. In no respect is his genius more apparent than in his management of nature, by which in general he instinctively seized upon her happiest moments and most beautiful aspects. The trivial and commonplace seldom found sympathy in him, because he felt that in interpreting nature his mission was to be faithful to her highest instincts.

The true field of Turner was the natural world. Whenever he aspired to the supernatural, as in the illustrations of Milton, and even the fanciful, as in some of those of Campbell, he failed. His failure is the more prominent from its position in the poems, which shows that in imaginative grasp and beautiful imagery he was not only unequal to those minds, but incompetent, even with their aid, to soar equally high; but when called upon to illustrate natural scenery or domestic life he then showed himself also a poet. His drawings have an exquisite sense of harmony. In gradations and variety he carefully studied nature. One of his chief merits is that he suggests more than he represents. Feeling is conspicuous in his work; consequently we fail to exhaust his work, but go to it again and again, ever discovering some new beauty or thought. We feel the inability of material to portray his complete idea. There is a sublimity of expression in nature beyond art to render, but of which Turner, more than any other artist, makes us sensible; indeed, in the making up of his landscape world, he condenses so much of the noblest and loveliest elements of the natural that we feel his ideal while recognising the truthfulness of the actual scenery. He catches the best expression of nature. While Turner has laboured as the prophet of nature to make us perceive her beauty and sublimity, Mr. Ruskin, in no less degree, has wrought as the apostle to make us comprehend her truths. To these two art-souls the world is more indebted than the present generation may confess. To name the drawings and engravings which stamp Turner as the greatest master of landscape would be to fill a volume, he was as prolific and various as he was cultivated. We see that he embodied both power and diligence. There are in him no traces of academic teachings, every line breathes of the pure school of nature. As a painter, however, he had not that same delicate feeling for colour that he had for form, or rather he sought to carry out in oil the same principle which gave him success in water-colours and failed in consequence of pitching his key too high. Those who seek to establish his reputation on this basis do him an injury and mislead the public in their appreciation of the harmony of colour. We can only judge of his oil pictures as we now find them. If Turner was careless or experimentive in his materials, so that his colours have not only become opaque, but are changed and even falling from his canvas, he lacked an essential feature of a great painter. On his engravings and drawings must rest for the future his reputation as an artist. There are great paintings of his still in perfect condition, but they are of his early days, when he prided himself upon triumphing over Claude, Salvator, Vandevelde and Cuyp, each in their particular excellence. He even made an attempt to copy Titian in colour. These pictures are sufficient to give him much reputation as a painter, but not to establish him as a great colourist. His power over water is more apparent in form than hue, which is slightly dry; but he so far excels all other artists, even in luminous liquidity, who have painted the ocean in mass—the quiet bits of water by Claude are not to be considered as ocean—that we think of failure in him only in comparison with nature itself. In his *Landing of the Prince of Orange*, how gloriously the barge lifts on the swell, which is all motion and passes away in the salt-mist that half-veils the distant vessels. There are brine and tar and bilge-water, the creaking of blocks and the running of ropes, the dull fog-muffled sound of cannon and the quick stroke of oars, the lazy pitch of the hull and the flapping of canvas in all this. We can cast hook and line in this water and they will go to the bottom; whereas with almost all other artists—even Stanfield's is viscid—St. Peter would have needed no miracle to have saved him from sinking.

Turner's fame as an oil-painter by some is made to rest upon his later style. In some of his recent pictures there are portions of colour that sparkle with light and are true to nature; but they are so rare, as we now see his pictures, as to seem exceptions to his general tone. In the pictures which he retained in Queen Anne Street Turner appears to have departed from all those qualities which make his water-colours so valuable. There is nothing of nature in them. Occasionally some familiar object is suggested, but there is no certainty, even after close study, of the motive and scarcely of the form. With many the time chosen, especially in the Venetian pictures, is when the sunlight is strongest, and we naturally fly from its glare. If his ambition were to rival nature's intensest light, he has, as all painters must, signally failed. The pictures present glaring white surfaces, spotted with positive colours, laid on with a dash of the brush or the fingers, with little or no attention to form, an intense blue for the upper sky, but all colour opaque, and the canvas so heavily loaded that in many places the paint has dried, cracked and dropped off. Where, as in the *Napoleon*, he has aimed at strength of colour, he has given only an unintelligible glare of blood-red and spotty-black over a white surface, on which form is almost wholly untraceable, so that the picture is more like an artistic nightmare than a coherent thought. His *Hail, Rain and Steam* is no less untrue to nature. The bridges are mere ghosts of substance. Both earth and water are equally destitute of quality. The sky is far more solid than the stonework. It has no luminosity whatever, but is actually falling to pieces from its own weight of paint. Even the locomotive, which should have the appearance of metal at least, is a mere phantom. The ironwork, which naturally suggests strength and capacity, is made up of a thin glazing of black. In short, he has reversed the first principles of painting, leaving solids transparent and making liquids solid, and pitching all upon so high a key as to offend the eye. It may be a freakish display of power, an endeavour to accomplish impossible ends through frail materials, or an attempt to dazzle by eccentricity, but it is not the labour of an artist rich in the experience of time, diligent and patient, and loyal to nature's truths. Too much strength to colour cannot be given. Its power lies in this. The tints must be harmonised and scumbled into luminosity, not left positive and opaque. Nature overpowers vision by her brightness; but in her most gorgeous sunsets the sky is full of cool, whitish greys, which amalgamate with and permeate the richer tints, giving them that quivering transparency which is so dazzlingly attractive. We want luminous and liquid air, and not plain white or blue paint, which Turner has given. His skies are spotty and hard. They do not illuminate. The bright atmospherical colours should appear of prismatic tenderness of outline and texture as in the rainbow, arching space. Solid pigments will not express the qualities of either sky, flesh, or water. Yet Turner lavishly employs them for these effects, and when he seeks to render solidity and dryness, gives an almost ethereal lightness of colour. So much faith had he in his method that he often relied on colour more than his drawing to suggest objects. The consequence is that in all this class of pictures he bewilders the mind by his palpable violations of the first truths of art. Titian, on the contrary, although relying on the enchantments of colour for his greatest effects, never disturbed its harmony by gross departures from the general unity of form and spirit. Turner occasionally indulged in mere tricks. Titian always worked on broad principles. The latter will live through all time by the permanency of his works. The former must depend upon the engraver for his general fame, while his highest merit can be known only to the few who possess or have the opportunity to study his best water-colour drawings.

Unfortunately for him engraving cannot do his varied powers, as exhibited in the minute gradations and subtle forms of nature, full justice. Neither does it thus far adequately represent Gainsborough, Titian, Raphael, Leonardo, or any great mind. Turner challenged comparison with Claude by hanging two of his works in the National Gallery at London,

between two of that artist's, one of which is an indifferent copy, and the other, if original, inferior to other Claudes. Turner is by far the greater artist. We find in him an imaginative power and feeling, in short, a genius, to which Claude was a stranger. He is great, however, in these pictures in parts, and not as a whole. His colour is hot and harsh, as in his *Building of Carthage*, and the attempt to eclipse Claude in his particular method of composition is too apparent. The latter, not in these two pictures, which by no means fairly represent him, but in those that are undoubtedly genuine, please more from their harmony of colour and general unity of nature's chief elements.

GIBRALTAR.

A PROMINENT American architect, Mr. A. J. Bloor, who has been travelling in various parts of Europe, has given in *Architecture and Building* the following account of his visit to Gibraltar, which has more than usual interest owing to the revived importance of the place :—

The first sight of the renowned rock of Gibraltar and stronghold of British power is, like that of Niagara and many another object of nature or art, somewhat disappointing, I fancy, to most observers ; but as one gradually takes in its sky-line and notes its steep and rugged sides, everywhere studded with masses or seamed and crossed with lines of defensive masonry, one soon realises that he is confronted by one of the greatest fortresses of the world. In fact it is, with its works, given I believe the first rank as a fortification by military authorities. Or at least it has hitherto held that rank, though whether the tremendous projectile appliances of recent years do not invalidate its reputation for impregnability must be left for them to say.

Apart from its importance to the modern world from the military point of view, this never-sleeping sentinel of the power that commands the Straits from which its frowning crags emerge—the gateway to the east—has other claims on our interest as the *Ultima Thule* of ancient civilisation, till the Phœnicians, from the other end of the Mediterranean, braved the mystery and unknown dangers of the untracked waste of waters to the west (compared to which, if they had but known it, their Great Sea, with its tideless water, was but a lake), and sailing northward ransacked the Cornish coast of England for its tin.

As our good ship came to anchor among eight or ten British men-of-war—several of them seemingly of the highest grade—and a few other vessels, naval or mercantile, flying the American or German flag, we found before us a solid sea wall apparently two or three miles long, with a town sloping upward from it and forming a short line, oblique and in some places almost vertical, on the left, till it terminated somewhat less than half-way up in an ancient looking building reminding one of the keep of a Mediæval castle, and which, on landing, my guide told me was a Moorish castle built by the first invaders of Spain from the opposite shores of Africa 1,300 years ago. From these remains the topmost structures of the town slope in a long, easy line downward to the right till the sea wall is reached. The town itself is a solid mass of buildings, civic and military, within these topping-out lines, which roughly form a long, narrow triangle. From the right-hand termination of the mass, carrying the eye further to the right, stretches a long space, nearly vacant except for vegetation, some of it quite tropical, and this is followed by another scattered collection of buildings, apparently a suburb of the town proper, and made up largely of military works. Beyond this settlement the rock still stretches for a considerable distance, and is crowned with several fortifications till it dips into the sea. Carrying one's vision backward to the left we find the rock terminating not far from the base of the thickly massed portion of the town ; and keeping one's glass always to the left, one sees a few rods further off a gateway guarded by sentries which, I am told, marks the limit of the English occupation on the peninsula. Beyond this stretches, for apparently a quarter mile or so, a flat space which is neutral ground between that and the Spaniards' town of Lina (an arena in front of which to the right is, we are told, devoted to bull-baiting), and which, as that word in their tongue is equivalent to ours for line, is evidently applied to it to indicate their first line of possession.

Turning round, with our back to the rock, we face the coast of Africa, but a few miles off, the town of Ceuta, in Morocco, being distinctly seen even with the naked eye. And here I have a little discussion with a *compagnon de voyage*, who contends that the base of a mountain visible at some distance to the left of Ceuta is surmounted, if only the thick clouds would permit us to see them, by two peaks which are what the ancients named the pillars of Hercules. Such recollection, however, as comes to me of my juvenile Latin exercises inclines me to the belief that the rock of Gibraltar itself (the Calpe of the classics) is one of the pillars, standing as the outpost for Europe, and having a counterpart on the opposite side of the strait as sentinel of the African continent. It seemed very odd when we turned to the guide-books at hand to find Gibraltar apparently forgotten. At all events, we could find nothing to settle the question, and on reflection it seemed to me that I could really recall less about the place than about any other on our itinerary.

Getting ashore in a small steam tender through a crowd of small boats laden with all sorts of fruit and gimcracks, vehemently offered for sale by "rock scorpions," Spaniards, Levantines, Arabs, Moors and negroes of every shade of colour and every variety of costume, we scramble up on the jetty and receive tickets admitting us within what I have been calling a sea-wall, but is, I find, the outer line of fortification and the seaward wall of a series of casemates, each well guarded by sentries. Over the interior wall of the gateway giving entrance from the water to the town is a marble slab inscribed with the information that it was built in a designated year (I quote from memory and seldom feel safe in recording dates without the exact figures before me) "of the reign of His Most Gracious Majesty George III., by His Royal Highness the Duke of Kent and Strathearn, &c., Governor of Gibraltar." The Duke of Kent was a son of that king and the father of the Queen-Empress who still rules over those vast dominions on which the sun never sets, after the longest reign in English history, and long may the reign last of that exemplary sovereign lady who for many years has never failed to send a quick and gracious message of condolence and sympathy on every occasion of public calamity in the Great Republic once a colonial appanage of her grandfather. British governorships, even its viceroyalties, have been usually administered by men below the upper ranks of the nobility, and the importance of Gibraltar to the British Crown may be estimated by the, I think unprecedented, fact that the rule of it has been held by a prince of the blood.

I was soon threading my way slowly along the main street of Gibraltar, parallel with the water, and up the narrow, winding, zigzag lanes ascending from it, structures of one kind or another for military use being met at every few steps, interspersed with little shops and houses of various classes, some of the latter having their lower windows grated and having oriel windows or balconies or both above. Those of sufficient importance to have been designed with any attempt at architectural *motif* may be described as having a Renaissance basis of rococo development. The lowest and main street was full of life and business, the freightage of merchandise being conducted in narrow carts drawn by horses, mules or donkeys, those with more than one beast being driven tandem fashion. Occasionally one saw three to the vehicle, reminding one of old times (and possibly of current times) in Philadelphia, with six or eight horses trotting in Indian file before their load. Small donkey carts also abounded, and light carriages, dog-carts, tea-carts—or whatever may be the current name for traps of that kidney—the whips wielded by smart-looking ladies, doubtless the better halves of officers of the garrison. Side by side with them trotted along patient little donkeys with a huge well-piled pannier swung on each side and almost hiding them from view, and not seldom, poor beasts, with the additional burden of a great lubberly fellow squatting between the panniers. The people who threaded their way among these vehicles were as motley as they, ranging, with all sorts of colours and costumes, from the smartly-groomed officer or civilian to the *gamin*.

Mounting the cross streets in all their devious ways we find the higher we go less bustle, fewer civilians, more soldiers, more walled and sentried enclosures, more fortifications, and everywhere cannon, cannon, cannon. We are passed, after requisite parleyings, through several enclosures, and, coming to a guard-house, are desired to register our names and addresses, and soon find ourselves surrounded by more embattled walls, more cannon, more soldiers, and no civilians but ourselves and several other little visiting parties. The "milingtary," as Dickens's Marchioness used to call the rank and file of her country's fighting force, are the same well-groomed young fellows—those on duty at least, which most of them in the enclosure are—one sees wherever an English garrison exists—dandified, as far as dandies can be made out of material most of which is rough enough originally, and most of them having that air of self-complacency and deputised world-possession which sits not unbecomingly on men who are taught, not in so many words, of course, but by the conditions and discipline imposed upon them, that their one duty is, at the call of their military superiors, to take their lives in their hands at a moment's warning as defenders of their Queen and country. To the civilian, and especially to the American civilian who is too young to have had a part in the civil war, there may be something offensive, or even ludicrous, in the individual bearing of the British rank and file ; but the private, though only an atom in the homogeneous military machine, is of good set purpose disciplined to recognise that each atom has its place in the whole, and he is led to practise carefulness and precision in greater things by making it obligatory on him to wear his natty little cap at a particular angle on his head, with the strap of it on a special line betwe en

his mouth and chin. His *amour propre*, representing his share of the self-respect of the entire *personnel* of the army, is nourished, too, by flourishing the jaunty cane he carries when not under arms. Several long sojourns in the Bermudas—that important mid-Atlantic military and naval depôt of the British Empire (it has the largest dry dock in the world)—having given me some acquaintance with the garrison ways of Tommy Atkins, and being somewhat tired of following up my little party's not always very coherent or very intelligible guide, it occurred to me it might be a good plan to secure one for myself in the shape of a private whom I noticed lounging about without cane or cap-strap and with other *negligé* signs of being off duty. Accosting him, I found him at liberty and more than willing, for a consideration, to pilot me within the famous galleries, the entrance to which we had now reached. First securing a pass for myself, we passed the sentinel and gatekeeper and entered the galleries, cut out of the solid rock more than a century ago (I noticed a stone in one of them dated 1789, coincident with the outbreak of the French Revolution) as a shelter for the inhabitants rendered homeless by the destruction of the town from the shells of the besieging Spaniards and French. The galleries are occasionally somewhat dark, but are generally fairly well lighted by port-holes cut out of their seaward walls, and in front of each opening stands a great cannon. The view from the ledges of the rock, to which there is an occasional outlet from the galleries, as one looks downward to the Spanish territory and across the straits to the African continent, is very fine, but did not prove sufficiently so to an enterprising if somewhat overdressed damsel attached to another American party than my own, and straggling outside of it in search evidently of the prey her kind affects.

My military guide was not a bad-looking young fellow, and he was evidently not adverse to her gradual approaches, for he buttoned up his jacket, tightened his belt and got his cap at the right angle with the strap in proper position. With an alluring glance at him and a half-bold and half apologetic one at me, she was soon at his side, plying him with questions as to the place and its inhabitants, especially its military contingent. After the manner of her sort her tones were more strident than musical, and her queries more indicative of fluency than of depth. Our bold soldier boy was in fact occasionally rather distraught under her rapid fire, and "Hi reely don't know, Miss," was his most frequent answer; but she checked her inquiries only to inform us of her place of residence "at home," and said she had never left it before except to go to the World's Fair in Chicago, and that she had then and there made up her mind that she was agoing to make a tour of the world and had given her pap no peace till he had engaged to take her part way this time and the balance for her wedding trip. Here she looked a little conscious and shy, but promptly recovered her self-poise, and taking hold of a button on the soldier's jacket said she would give him "a quarter" for it. She wanted to take it home as a "souvenir." She was agoing to get souvenirs of soldiers' buttons in every country she visited; they would be such nice, small, handy things to carry home as souvenirs; she could get any quantity of them in her satchel. Our Tommy looked somewhat blank. "Well!" she said," "if a quarter ain't 'nough I'll give half a dollar. I'm bound to begin my c'llection right away. Mebbe you can lend me a knife?" turning to me. It is my way to carry two penknives, one for real work and the other a smaller and nicer one, to meet just such cases, to wit, the call of ladies for a loan of something to cut with. But on this occasion I gave no sign of even single possession, and told her with impressive solemnity that such was the tyrannous discipline prevailing in the standing armies of the effete monarchies of Europe that an unfortunate private would probably be flogged within an inch of his life if appearing on parade minus a button belonging to his uniform. The young lady, as she listened, was evidently divided in her mind between commiseration for the unhappy youth's perils, the suspicion that I might be guying her, and the impulse to raise her bid for the coveted initiatory button to a dollar; but as our guide confirmed to some extent my assertion as to the punitive results of missing buttons, she was evidently nonplussed. By this time I felt that I had some claim to my own extemporised cicerone, and observing a couple of nice-looking young fellows standing before an adjoining port-hole, I directed our fair companion's attention to the superb view to be had from it. She promptly swallowed the bait, and the next moment the enterprising damsel was beside my two opportune youths and thanking them for making way for her. Whispering to my guide that she didn't "belong to me"—for he had evidently supposed she did—I slipped off with him, and we pursued our way among more cannon and port-holes. After awhile I got tired of the monotony as well as of the climb itself, and declining my guide's invitation to mount to a second storey of the gallery, which he admitted was but a repetition of the lower one, "though you know, sir," he added, "the 'igher hup you goes the more you sees of the fine prospecks," I took a last lingering look towards the waste of waters we had just crossed and began to retrace my steps. On our way back we met our young lady chatting and laughing between the two youths she had captured in front of the fine view I had pointed out to her, and both cavaliers were evidently quite in the frame of mind habitual to our old friend Barkis.

Returning to the entrance of the gallery I bade my guide good-bye, and after a good look at what remains of the Moorish castle, I leisurely traversed my way down the narrow streets and lanes in the direction of the Alameda, the park and Rotten Row of the place, which, while our parks at home are probably hidden in snow, show sub-tropical vegetation in full condition, some of our own flowers being also abundant, especially fine examples of the geranium.

While in the galleries I had been on the *qui vive* for the indigenous monkeys I had read about, and my guide had told me there was "a plenty on 'em sometimes, and they got in at the winders and made a great racket," but the only monkeys I encountered—and those outside of the military precincts—were of the ubiquitous species, most mischievous of all, the small boy. One of these, "born on the Rock," he told me, offered me for "a ha'penny" two of the military buttons coveted, at a cost of two shillings sterling, by our young lady would-be collector. They had been skilfully manipulated and crushed together so as to look at first glance like ancient coins, and as such the little "rock scorpion" offered them, emulous of the trading tricks of his betters. From another, a newsboy also "born on the Rock," I bought a copy of the Gibraltar *Chronicle* headed with a woodcut of a castle, having a large key under it, indicative of the location's relations to the Eastern World, while the motto beneath, "Montis insignia Calpe," shows that my memory was correct at least as regards the classic name of the Rock, and I think it is not less so as regards the Rock itself being one of the pillars of Hercules.

As we steamed out of the harbour and there came into full view the side of the Rock against which abuts its back, a sheer precipice, ending far up at top with seemingly a mere pathway of flat surface, I fancied that I saw before me the rough-hewn outline, carved by some Michel Angelo among the Anaks, of a nude human figure, stretched out prone on top of the rock, his back toward us, the elbow of his right arm resting on the rock and his head on the palm of his hand, with his lower limbs stretched out at full length and his left hand resting on his hip. Or rather, an awful figure not hewn from lifeless stone, but a huge giant who had drifted, long ages ago, across the Atlantic from the western world, and, seeking rest before re-embarking on the tideless waters that divide Europe from Africa, had, while taking a last look backward, fallen into the sleep which knows no waking and been turned into stone like that on which he slumbered.

While in this imaginative vein I recalled the sketch I had made from our vessel's deck of the front of the Rock while waiting for our tender, and taking my sketch-book from my pocket it seemed to me I saw before me, though it had not struck me while making the sketch, the outlines—rough, of course, but even more distinctly defined than those of my imaginary rock-turned Red Indian—of the British lion, in the attitude called in heraldry *couchant*, stretched at full length above the Straits it guards, its shaggy head resting on its front paws and its hind legs thrown out to their full length backward; a lion at rest, but ready to spring up at a moment's warning, and, when danger draws nigh, send its roar of warning and defiance from one end to the other of the Empire whose drumbeat is heard all round the globe, and sound the note of the best practicable colonisation for the surplus population and energies of the mother isles, and of the best attainable recuperation and civilisation for the worn-out communities and waste places of the world, preliminary to that higher civilisation when, under the influence of new and space-annihilating appliances, born of electricity and its probable sequences of other latent physical (to say nothing of spiritual) forces now undiscovered, the racial differences of the past and present shall be forgotten by the new and cosmopolitan race resulting in the future from the commingling in one strain of the special forces, adaptabilities and virtues of the former various races.

ARTISTS' COPYRIGHT.

THE Select Committee of the House of Lords on Copyright met on the 14th inst., when Mr. John Scrutton, barrister-at-law, put in a copy of a report which he had made to the Board of Trade on the two Bills before the committee, and in which he had suggested, clause by clause, points for the consideration of the department. He expressed a strong opinion that instead of attempting to deal in a single clause, as Lord Herschell's Bill did, with the different kinds of copyright, it would be desirable, so far as rights and infringements were concerned, to keep all the different subject matters of copyright separate. It would only lead to confusion to attempt to put into one clause a form of words which would cover such different subject matter as books, pictures, plays, sculptures, and

so on. There was a great difference in "publication" as applied to works of art and as applied to books. There was no difficulty in ascertaining where a book was published, but there was enormous difficulty in ascertaining where a work of art was published. Any person, for example, who tried to discover where a work by Sir E. Burne-Jones was published would probably find that it was practically impossible to make publication a test of the commencement of copyright. No right was obtained by publication under the copyright law relating to artistic works. Copyright in that case vested on the making, and there was side by side with that a common law right, and the effect of publication was to divest the common law right. Without publication the common law right and the statutory right ran side by side. If the artist never published his picture and never registered he would still be able, as would also his descendants, to stop any other person from making copies so long as it was desired to keep it unpublished, but until registration the protection of the statute could not be obtained by way of penalties and other remedies. He did not say that publication in relation to artistic works was incapable of definition, only it would be a good thing for the lawyers.

The Chairman: Is there any objection to annexing the right to penalty to the common law right as a remedy?—It would materially strengthen the common law right and I see no objection to it.

With regard to the definition of publication in the case of books, he thought the law would treat a book as published when any person could obtain it by going to the particular place where it could be got. He suggested that the committee should deal with this question in relation to works of art published in the United States. At present, owing to an unfortunate slip in the law, works so published were not protected at all, and many citizens of the United States felt it to be a grievance. The author of an artistic work, such as paintings and engravings, made in the United States could not get copyright in England. The United States law was passed on the understanding that it gave copyright both for books and works of art published in England by persons living in the United States, but while that was the case in regard to books, it was not so in regard to works of art.

The Chairman announced that the committee had come to the conclusion, looking to the advanced period of the session, not to proceed with further evidence, but to report the evidence so far as it had gone, and to recommend the reappointment of the committee for next session.

THE PERCEPTION OF COLOUR.

ON Monday the annual general meeting of the Victoria Institute was held in the rooms of the Society of Arts. Sir G. Stokes, F.R.S., the president, delivered the annual address. Taking for his subject "The Perception of Colour," he observed that all scientific men recognised the imperfection of their knowledge with regard to the perception of colour. Something had been done experimentally, partly by way of establishing certain laws as to the direct perception of colour, and partly by way of investigating other perceptions which might guide them by analogy towards forming some conception of the requirements demanded in our bodily organisation for the perception of colour. The subject lay on the borderland between physics and physiology, but so far as his own knowledge extended it seemed to him that there was one theory which had by far the greatest amount of probability. That was the one known as the "Young-Helmholtz" theory. It was now universally admitted that light consisted of vibrations. They sometimes said that colours harmonised, but there was absolutely no phenomenon known in light answering to the sensation of harmony in sound. It had long been suspected that in light there was a kind of triplicity, that three kinds of light would give all the sensations of colour by mixing them together. Some had speculated on the possibility of there being an objective quality in light answering to redness, greenness, or blueness, or whatever trio of colours might be taken, but there was absolutely nothing objectively in light that they knew of which answered to redness as such, yellowness as such, or blueness as such. Dr. Young believed there were three primary sensations of colour, and that they were called up simultaneously when any colour was presented, but in different proportions according to the nature of the colour. Those primary sensations were red, green and violet. Those might be taken as the three standards of colour, because by their mixtures the other colours could be most closely reproduced. That theory was taken up by Helmholtz, and was now known as the "Young-Helmholtz" theory. Under this theory three classes of nerves were brought into play, and what scientific men had now to explain was how it was that the stimulation of these nerves produced the three different sensations which he had spoken of as primary. Helmholtz had advanced the theory that it was due to some photo-chemical action, and possibly there might be something in that suggestion. At any rate the subject was a very difficult and speculative one, but it led to some interesting contemplations. One thing they could not fail to be strongly impressed with was the wonderful complexity of that marvellous organ the eye and its retina, and the proof which, to his mind, it gave of design in its construction.

Lord Kelvin, in moving a vote of thanks to the President for his address, observed that the "Young-Helmholtz" theory of the perception of colour was now universally accepted among scientific men all over the world.

Lord Lister, in seconding the vote, remarked that, among the many hypotheses on the subject, of this, at any rate, they might be sure, that the different sensations experienced in the perception of light did not depend on differences of construction in the individual nerve fibres, but on the nerve fibres being called into action by a certain stimulus.

The vote of thanks was passed unanimously.

THE LOCKWOOD MEMORIAL.

THE following is the report of the sub-committee appointed to consider the appropriation of the money subscribed in order to raise a memorial of the late Sir Frank Lockwood, Q.C.:—"The sum received from subscribers amounts to 1,250*l.* It is unnecessary that any further subscriptions should be solicited. Your committee recommend that this sum shall be applied in the following manner:—(*a*) To the endowment of a child's cot in the London Hospital, to be named after Sir Frank Lockwood, 500*l.*; (*b*) to obtaining a portrait of the late Sir Frank Lockwood, to be eventually offered to the trustees of the National Portrait Gallery, 420*l.*; (*c*) to erecting a stained-glass memorial window in York Minster, 175*l.*; (*d*) to erecting a memorial brass in St. Margaret's Church, Westminster, 50*l.*; (*e*) to the purchase of a portrait of Sir Frank Lockwood, to be presented to Lady Lockwood, 105*l.* The above expenditure amounts to 1,225*l.* "In respect to the endowment of a cot your committee recommend that the nomination to such cot should be vested in Lady Lockwood or a person named by her, with power to transmit such nomination. Your committee have communicated with Mr. Arthur Cope and recommend that he should be selected as the artist to paint the suggested portrait. Your committee have communicated with the Dean of York on the subject of the erection of a window in the minster. No direct reply has been received from him, but your committee are informed by Sir Frank Lockwood's executor, who is resident in York, that the Dean will give every facility for the erection of the proposed window. Your committee have learnt from Canon Eyton that he will gladly authorise the erection of the proposed brass in St. Margaret's Church, Westminster. An excellent portrait of Sir Frank Lockwood has been painted by Mr. J. F. R. Wood, which can be inspected by members of the general committee. It is thought that Lady Lockwood will value the possession of this portrait. It will be seen that there is a balance in hand, as to the allocation of which the sub-committee seek the direction of the general committee.

TESSERÆ.

A Window as a "Casus Belli."

THE war of 1688, so fatal to France, was occasioned, says M. le Duc de St. Simon, by a paltry dispute about a window between Louis XIV. and Louvois, his Minister of War, which showed the character of the monarch and the minister so clearly that he felt it to be his duty to give a correct account of so strange a cause for war. Louvois on the death of Colbert was appointed superintendent of public buildings. The small Trianon de Porcelaine, built originally for Madame de Montespan, displeased the king, who rejoiced in nothing but palaces, and amused himself in building them. He possessed a very correct eye for proportion, regularity and symmetry; but for pure taste, he possessed none. In rebuilding this palace, when it had scarcely risen above the level of the ground, the king espied a defect in the arrangement of one of the windows of the ground-floor storey. Louvois, who was by nature surly, and so spoiled as scarcely to receive any rebuke, even from his royal master, disputed the point forcibly, and maintained that the proportions of the window were correct. The king turned upon his heel and walked away to another part of the building. The next day he met Le Notre, the architect, whose taste in ornamental gardening had embellished Versailles, St. Cloud, Chantilly, the Tuileries, Greenwich, Windsor, St. James's, &c., had been rewarded by his sovereign with riches, knighthood and nobility, and by the verse of the poet of gardens, Delille. The modern Alexander demanded of the Gallic Dinocrates whether he had been at Trianon.

The architect replied that he had not. The king explained how he had been offended, and desired him to see the peccant window. The next day the same question and the same answer, and the following day similar repetitions. The king plainly saw that Le Notre was equally afraid to discover wrong in royalty as to blame the powerful minister; Louis became angry, ordered the hesitating architect to be at Trianon on the morrow to attend him and Louvois. Le Notre could no longer parry the royal thrusts; the king met them both, as appointed, at the new building, and his first inquiry was concerning the window. The architect said nothing, the king commanded him to measure and try it by line and square, and say how he found it. While he was thus occupied Louvois, incensed at the anticipated verification of the king's correctness, grumbled aloud and angrily maintained that the window corresponded in every respect with the others. When the examination was finished, he asked Le Notre how it was, who hesitated. The king flew into a passion, and commanded the stammering architect to speak plainly, which he did, by avowing the king to be right and the window defective. He had scarcely finished when the king turned to Louvois, told him to give up his obstinacy; that the window was all awry and must be rebuilt, when at this time the building should have been finished; and rebuked him sharply. Louvois, incensed at this sally in the presence of courtiers, workmen and servants, went home in a furious rage. There he found St. Fouange, Villeneuf, the Chevalier de Nogent, the two Tilladets and other intimate friends, who were alarmed at seeing the minister in such a state. "It is done," he exclaimed; "I have lost the king's favour for a paltry window. I have no other remedy than a war that will draw him away from his buildings and render me necessary; and, faith, he shall have it." In a few months this vile threat was accomplished, and in spite of the king and other Powers, he involved his country in a general war, fatal and disgraceful to France at the end, although distinguished by many successful and gallant actions in its course; and which, perhaps, conduced to the success of the Prince of Orange in accomplishing the glorious revolution of 1688, and all through a quarrel about a French window.

Bookcases of the Ancients.

Every monastery in Greece, says Ricaut, has its library of books, which are kept in a lofty tower; and this fashion, possibly very ancient, was certainly adopted here from superior seclusion. Libraries existed in Egypt contemporary with the Trojan war, and one was formed at Athens by Pisistratus, long before the time of Aristotle, who, Strabo says, was the first Greek who made a library. The Romans borrowed the fashion from the Greeks, and the former had superb libraries, adorned with portraits of deceased *literati*; cases reaching to the roof, called "loculamenta," with shelves ("pegmata") and holes for the rolls ("nidi"), the walls between the cases being encrusted with plates of ivory and coloured glass. The cases and desks were made of ebony and cedar. The pavements were of marble and there were porticoes for readers. Duplicates of books were called "fratres," and all the works of an author were put, with his portrait, in the same place. These, however, were superb structures, belonging to the public or the great. The room at Herculaneum in which the rolls (not less than a thousand) were found was a mere closet, and Juvenal says that the poor poet Codrus kept his books in an old chest. But we hear of cabinets for books, which cabinets were numbered, stood in the vestibule, and were charged with ornaments repeated on the envelopes of the books. A library found in a ruined villa under the wood, belonging to the church of the Augustines, near Portici, was adorned with presses inlaid with different sorts of wood, disposed in rows, at the top of which were cornices as in our own times. Among the Egyptian monks the books were kept in a window, by which we suppose is meant an arched cupboard in the wall, the depository among the Britons, and apparently the Anglo-Saxon "boc-hord," for it appears in the frontispiece of Trivet's "Annals," engraved from the ancient illumination. The famous Godiva gave the monks of Worcester a bookcase divided into two parts, and we find elsewhere painted presses, chests, shelves and versatile desks called "rotæ." A very elegant one consists of a tall post or stand upon claw feet, surmounted by a large eagle. The shaft is cut into a screw for raising or lowering a round desk which encircles it.

Devices in Painting and Sculpture.

A device is an emblem or metaphor, which represents one object by another which bears some resemblance to it, such as a motto, a fanciful composition of small size, composed of attributes rather than principals, or an emblem used on a shield to indicate the rank, person, family, derivation of the wearer, or of the nation to which he belongs. The heroes of Greece wore different devices and inscriptions upon their shields. The Theban warriors carried the emblem of a serpent for their device, to indicate that they derived their origin from the serpent's teeth that were said to have been sown by Cadmus, the founder of their city and race. Æschylus has described in his "Seven Chiefs against Thebes" the bucklers of the chieftains, by the dramatic agency of the soldier, who is communicating to Eteocles the names of the seven heroes who are selected to attack the gates and the description of their appropriate armour. Their bucklers bore both devices and inscriptions. That of Capaneus had the figure of a naked man armed with a torch, inscribed in letters of gold, "I will burn Thebes." Upon that of Eteocles a warrior scaling a castle, saying, "Mars himself shall not repulse me." On that of Polynices, the brother of Eteocles, the figure of himself led by Justice, bearing for his motto, "I will re-establish him in the city and palace of his father." The usage of devices was practised by the people of the earliest antiquity, but they did not use them to the extent of some modern nations, mostly affecting a greater clearness in their inscriptions, and placed their allegories in images. Of modern devices that of the representation of a fish, indicating through the initials of its Greek name ΙΧΘΥΣ is the most celebrated, and perhaps the most perfect device or anagram extant. The Α and Ω placed on each side of the cross is rather more to be considered as a monogram than a device. Father Lemoyne considers the French to have been the inventors of devices, which is certainly untrue, but that they have used them to a considerable extent is well known. They have been the foundations of modern heraldry, which has been carried to great perfection by that people. Some of them are very clear and intelligible, such as the figure of a star, with the motto "Monstrant regibus astra viam," which was the device of the knights of the Order of the Star, instituted by the French King John. The representation of a fowling-piece, with the inscription "Ante ferit quam flamma micet," of the Dukes of Burgundy. René of Anjou, king of Sicily, having lost his wife, to whom he was much attached, took for his device the figure of a bow with its string snapped in twain, with the Italian motto "Arco par lentar, piaga non sana." Valentine of Milan, wife of the Duke of Orleans, who was assassinated at Paris by the orders of the Duke of Burgundy, assumed after his death, for a device, the emblem of an empty watering-pot, with the words "Plus ne mest rien, rien ne m'est plus." Louis XII. assumed the figure of a porcupine, inscribed "De loin et de près," to intimate his power of wounding close or at a distance. Devices may in this manner be composed upon most occasions, but they are in many instances only pictorial punning, alike removed from good taste and genius in art.

Greek and Roman Stables.

The Greek stable was to be so contrived with respect to the house that the owner could see his horse frequently, and the stall was to be so managed that it would be difficult to steal the provender out of the manger. The floor was to be sloping and on a declivity, and made of stone, each stone being about the size of the horse's foot. The groom was to lead the horse out of the stable when he was to be cleaned and dressed, and after the first meal to remove or turn him from the manger, that he might return to his second or evening food with fresh appetite. They were muzzled when cleaned and the groom stood sideways. In the stable they were confined by a halter to the manger. The litter and dung were removed every day. The stable-yard was paved with round stones, with a ridge or border of iron for keeping them together, hardening the hoofs, &c. Besides the stable-yard was a rolling place for the horses to roll themselves in. In the Roman stable we find rails to separate the horses, and the patena or manger of a rack, images of gods painted upon the stalls, a painted portico annexed to the imperial stable and lodgings of grooms near them, for so commentators interpret Caligula's stopping in a stable to sup. Stables to the present day are dark, and the ancients had an idea that darkness contributed to fatten animals.

George Jamesone.

Jamesone has been called vain because he often painted his own portrait, and ever with his hat on; but it should be remembered that this wearing of the hat was the practice of his great master Rubens, and that when his portrait was commissioned by a customer it became a duty to paint it. It was also, perhaps, in imitation of Rubens, that he usually introduced the portrait of his wife with that of his son and himself. Isabel Tosh was a comely woman, and the artist no doubt was vain of her good looks. His disposition appears to have been amiable; he painted many portraits for fame or for friendship alone, and bequeathed some of his most valuable works to the noblemen who had patronised him, thus at once repaying them for their kindness and securing for his productions galleries worthy of their merit. About his hours of study or his modes of labour who shall instruct us? He painted commonly on a grey canvas; his full-length portraits were usually a slight degree less than the life; his earliest works are sometimes on board and sometimes on cloth smoothly primed with a proper tone to help the harmony of his shadows. "He was one of the most

esteemed," says Walpole, "of Rubens's scholars, and painted in the broad, thin, transparent manner. His excellence consists in delicacy and softness, with a clear and beautiful colouring; his shades not charged, but helped by varnish, with little appearance of the pencil. He had much of Vandyke's second manner, and to Sir Antony some of his works have been occasionally imputed." This is high praise, but when we consider the state of British art in his day, and especially the unskilfulness of the native professors, it can scarcely be considered as extravagant. To depart at once from the formal corpse-like system of making figures, and assert the grace of form and the colouring of nature required boldness as well as genius, and there can be no question that Jamesone did all this. It may gratify certain sorts of critics to dwell on the undoubted facts that a certain hardness of manner is visible even in the happiest of his works; that his portraits are often of a severe aspect, with a touch too much of the vinegar of the times in them; and that he has reached but seldom the perfect ease and happy gracefulness of nature. His outlines are correct, his colouring lucid, and his proportions just; and he was the first native of our island who refused to limit himself to miniatures, like Hilliard and Oliver, and transferred life of the natural dimensions to his canvas. That he stands at the head of the British school of portrait painting there can, therefore, be no question, nor had England an artist of her own worthy of being named above him in his own walk before the days of Reynolds. When we consider the circumstances of the painter and his times—his want of instructors and models and the various difficulties which the fanatical prejudices of that dark age must have presented to any cultivator of the graceful arts—it is impossible not to admit that Scotland has all reason to be proud of George Jamesone.

Sketches on Canvas.

The painter is recommended to paint the sketch previously on canvas, as was the practice with Rubens. This method of painting the sketch, instead of merely drawing it on paper, will give a facility in the management of colours and in the handling which the Italian painters, not having this custom, wanted; by habit he will acquire equal readiness in doing two things at a time as in doing only one. A painter if possible should paint all his studies, and consider drawing only as a succedaneum when colours are not at hand. This was the practice of the Venetian painters, and of all those who have excelled in colouring. Correggio used to say, "Ch' avea i suoi dessegni nella stremità de' pennelli." The method of Rubens was to sketch his composition in colours, with all the parts more determined than sketches generally are; from this sketch his scholars advanced the picture as far as they were capable, after which he retouched the whole himself. The painter's operation may be divided into three parts: the planning, which implies the sketch of the general composition; the transferring that design to the canvas; and the finishing or retouching the whole. If for despatch the artist looks out for assistance, it is in the middle stage only he can receive it, the first and last operation must be the work of his own hand.

Runciman's Wall-Paintings at Pennycuick.

Historical painting became the confirmed idol of Runciman since he beheld the wonders of the Sistine, and he was no sooner settled in the North than he submitted the design of a great national work to Sir J. Clerk, namely, to embellish his hall at Pennycuick with a series of paintings from Ossian. This was agreed to at once. The poems ascribed to the blind old man of Morven were at that time in all the full-blown splendour of fame; the singular boldness of the style—the wildness of the imagery—the deep, heroic and chivalrous feelings which they breathed rendered them universal favourites, and when it is considered that a nation's vanity was involved in their history, and its character emblazoned on every page, no wonder that Scotland eagerly received and adopted what was announced as the offspring of her own cultivated genius produced at a period when all other European nations were barbarians. The reigning wits of England meantime looked on with distrust or derision; Johnson, Goldsmith, Burke, Garrick and all that coterie, together with Boswell, whose natural prejudices were as nothing to his worship of Johnson, amused themselves with lampoons in prose or verse against Fingal, Temora and the whole race of Celtic poems, whether epic or lyric. When it was told that Pennycuick was to be adorned with a series of paintings from those works, and that the hall was to be called Ossian's Hall, the mirth of these unbelievers knew no bounds. Men of talent are, however, seldom driven from their purpose by the malice of wit or the bitterness of humour. Runciman, content to receive for truth what his own nation believed, read, studied, sketched and imagined he saw in those effusions a series of fine historical subjects such as would make the hall of Ossian a rival to the Sistine Chapel. And supposing Ossian to be authentic, Runciman was right; the works of art with which a nation adorns herself should be from her own story, and to seek in Scottish poetry for his subjects was surely wiser far in a Scottish painter than to have recourse to the trite and hopelessly defunct mythology of Greece. The heroes and spirits of heroes and wild divinities of the Celtic bard had, moreover, the recommendation of novelty, and, finally, whether some ancient Highlander did or did not produce the whole, or any particular passages, no man now disputes but that the pages of "Ossian" do abound in poetry of the highest order. Sir J. Clerk readily entered into the feelings and wishes of the painter; sketches were made and approved, scaffolds raised, and to work he accordingly went with all the enthusiasm of one who believes he is earning an immortal name. But there is no work, however much it may be the offspring of one's own heart, that can be accomplished perhaps in the same spirit in which it was commenced. Men of taste, connoisseurs, patrons of fine arts were ready, with their dissonance of opinion, to excite pain in the mind of a sensitive artist; pain of mind was aggravated by pain of body; he had to lie so much on his back, while occupied with the ceiling of the hall, that his health failed, while, to add to other vexations, the searching spirit of inquiry and criticism began to sap more and more the lines of circumvallation within which Macpherson had entrenched himself, and that Fingal lived and that Ossian sung began to be doubted even among the Scotch. He painted on, nevertheless, and finished his very romantic undertaking.

Early Scottish Paintings.

Of the elder artists of Scotland and their works little has been either said or written. A few names and dates and references have been preserved in the Royal Book of Accounts The first name on the royal record is evidently a native one—it is that of John de Linlithgow, who, in the year 1329, sculptured the tomb of the great Robert Bruce; the second is that of "Andrew the painter," who made a monument in memory of David Bruce and his queen. Artists in those days were both sculptors and painters, and it was the fashion to paint and gild and inlay with precious metal and with precious stones the recumbent statues of our sepulchral monuments. Nor were the labours of those men confined to the church. The great hall in the castle of the renowned Randolph Earl of Murray was a work of no common magnificence, and must have cost much money and time. It was 89 feet long, 35 feet wide and 30 feet high, roofed with massive beams of carved oak and ornamented with sculptures. The oaken dining-table and chair of the warrior are still preserved; the former stands on six pillars, curiously bordered and inlaid, and the latter, in shape and fashion not unlike the old coronation chair in Westminster Abbey, is emblazoned with carvings of his family arms and emblems of his station as regent. Paintings in fresco, and even in oil, existed in Scotland from an early period. They were chiefly Scripture pieces or portraits of distinguished men. One likeness in fresco, of William the Lyon, is supposed to have belonged to the monastery of the Trinity Friars of Aberdeen, of which that king was the founder. It measures 4 feet high by 2 feet 9 inches wide, and bears the following inscription, of course of a later age than the picture:—"St. William, King of Scots, surnamed the Lyon, the first founder of the Trinitie Friars at Aberdeen, where he had his chappell, the chief place of retirement for his devotions. He reigned forty-nine years, beginning 1165, dyed at Sriveling 1214 and was buried at Aberbrothwick." In the parish church of Houston, Renfrewshire, were preserved the effigies or portraits of Sir John Houston and his lady, which belonged to a series of monuments commemorating the house of Houston. The knight is in complete armour, his lady, Mary Colquhoun, is in the dress of the time, 1400; they closely resemble the works of the same period still preserved in England. The portrait of Cardinal Innes in the collection of the Scottish Society of Antiquaries is believed to be the work of foreign hands. He is represented in the act of composing; books occupy the background, and an inscription says he is a native of Scotland, flourished in the year 1412, and wrote these volumes. Pinkerton assigns to the year 1430 the following story, in which barbarous deeds mingle with art perhaps equally barbarous:—A Highland robber having stolen a poor woman's cow, she vowed to wear no shoes till she told the king. On this the savage seized her, and, in ridicule of her vow, nailed horseshoes on her feet. On recovering, she went to the palace, told her story, and showed the scars on her feet. The monarch caused the savage to be secured and tried. On conviction he was clothed in a canvas frock on which was painted a man fixing horseshoes on a woman's feet, exhibited two days in the streets of Perth, and then dragged at a horse's tail to the gallows and hanged. James I. of Scotland, a poet of no common genius and a musician of some skill, was also a painter of miniatures and an illuminator of books. None of the works of this royal pencil have reached us, but he who could write with such good feeling could no doubt imagine works of art worthy of living. Illuminated manuscripts and miniatures are perishable matters; and, not to speak of time and bad

keeping, the fire of the reformers found its way so effectually among libraries that few works of that period remain ; one only, Fordun's "Scotichronicon," containing only some four or five illuminations, is preserved among Bishop Parker's books in the library of Christ's College, Cambridge. Heraldic painting, a sort of hieroglyphic history of families, was long popular. On the execution of Murdoc, Duke of Albany, and his sons, in the year 1425, they were buried on the south side of the altar in the Black Friars Church at Stirling, and over them were placed paintings of their persons and their coats armorial. In the reign of the saints in 1643 this sort of harmless emblazonment, which had survived Knox and all his fierce companions, was declared infamous. The General Assembly of the Kirk perceived something of Baal and Ashtaroth in the armorial bearings suspended in places of worship when persons of note or family died, and passed a prohibitory Act "against burials and hanging of pensils and brods, and offering of honours and arms, and such like scandalous monuments, in the kirk." Having destroyed their splendid abbeys, they possessed, no doubt, in those days few kirks worthy of hanging either pensils or honours or arms in.

Palladio's "Teatro Olimpico," Vicenza.

Admired at first, because then superior to anything of the kind, it has continued to be admired since, partly on account of the character attached to it, which few care to dispute, and partly perhaps on account of its singularity, and because it shows the peculiarities of the ancient theatre. By no means, however, is it a very accurate imitation, though its chief merit lies in being a mere imitation ; it is semi-elliptical instead of semicircular, with the stage on the longer axis of the ellipse, wherefore it looks too much squeezed up one way and stretched out the other, and produces the same kind of disagreeable effect as would arise from placing the stage on the longer side of a parallelogram of the same extent (96 by 45 feet). It is said that the space to which the architect was restricted compelled him to adopt that form, yet it hardly appears so from the published plans of the building, for it would not be difficult to show how a semicircle might have been brought in. With regard to the scena, for which unlimited admiration is claimed, nothing can be more tasteless ; it abounds in almost as many architectural barbarisms and solecisms as could well be brought together. Even Robert Adam spoke of it as mere "gingerbread," and another architect, Wood, says, "The scene, which is the part most admired, borders upon trumpery," and that although the building "is too celebrated to be omitted, for him it might have slept in oblivion." It is not, however, so much the scena or facciata itself as the avenues seen beyond it through the centre arch and other openings which attract notice, and have been extolled by some as greatly superior to the "flimsy" painted decorations upon canvas used in modern theatres. Those avenues represent as many streets, the fronts of the buildings being modelled or carved in relief, and attempted to be shown in perspective by the floor and ceiling sloping very much upwards and downwards, and the other horizontal lines accordingly, and by the passages themselves being narrower at the further end. The contrivance is puerile at the best, and instead of being more deceptive or natural than painted scenery the imitative perspective becomes distorted when viewed from any other situation than the centre of the theatre and the level of the stage. It is also difficult to understand how these narrow enclosed passages could have been properly lighted at the time of a performance, and although they are, in stage language, "practicable," hardly could they have been made use of, at least not for their whole extent, because at their further end an actor would appear gigantic. This structure is nevertheless entitled to notice as an example of a very defective and faulty system, and because it has been frequently mentioned for the purpose of recommending, on the imposing authority of the name of Palladio, what ought not to be imitated.

The String-Course.

String-courses admit of great variety, and contribute very much to decoration, while they are in themselves essential members, inasmuch as they serve to define the internal division of the building, corresponding with the floors of the several storeys; and by separating one tier of windows from another, to mark each as a distinct portion of the general composition, complete as regards itself, though secondary to the other. While they separate they serve also to connect and combine the successive stages of a building, and to produce a due mixture of horizontal with perpendicular lines. In Gothic architecture the upper surface of a string-course is almost invariably splayed or sloped in order to shoot off rain, the projection being usually such that the wet would else lodge upon it. The string-course itself consists sometimes of only a few narrow and plain mouldings, at others of a variety of them separated by one or more considerable hollows. In the later or perpendicular style of Gothic the string-course is frequently made a broad tablet, not only richly moulded, but ornamented with sculptured blocks, heads of animals, shields, &c., placed at intervals in the principal cavetto or hollow, besides which, additional carved ornament is occasionally introduced on the surfaces between the other mouldings. In some instances the string-course is so enlarged as to become a sort of frieze or horizontal panel filled up with a pattern of tracery, or with lesser panels, &c., carved on it. In Italian architecture the string-course (*fascia*, Italian; *cordon*, French; *Band*, German) is either quite plain, or more or less decorated according to the character of the floor to which it belongs. That which crowns a basement floor is seldom more than a plat-band or plain surface, while the upper ones form ornamental fascias, enriched with guilloches, frets, &c., either with or without mouldings.

GENERAL.

Dr. Charles Hunter Stewart has been appointed by the Edinburgh University Court professor of public health and sanitary science. Dr. Stewart was chief assistant in the bacteriological laboratory connected with the chair of medical jurisprudence and public health in the university.

Sir J. Wolfe-Barry has been elected chairman of the council of the Society of Arts.

Plans are being prepared for a military hospital for the Portsmouth Garrison, which is to be erected at the foot of Portsdown Hill.

The Directors of the New Gallery have decided to hold next winter an exhibition of works by the late Sir E. Burne-Jones, and they have pledged themselves that, after the payment of rent and other incidental expenses, the proceeds of the exhibition shall be added to the amount that has already been raised by public subscription for the purpose of presenting a work by the painter to the National Gallery.

Mr. Gordon P. G. Hills, 4 Adam Street, Adelphi, has been successful in the competition for the new Board schools to be erected in Littlehampton.

Applications for space in the British section of the Paris Exhibition must be made before August 20 next. It is therefore desirable that manufacturers and others wishing to exhibit should send in early applications for space to the Secretary of the Commission, St. Stephen's House, Westminster.

Mr. Thomas Brock has been entrusted with the commission for the national statue of Mr. Gladstone, in Westminster Abbey.

The Directory of the Department of Science and Art, revised to June 1898, was published this week, and contains several important changes of the regulations.

The Gladstone Memorial Committee propose to erect "such monumental memorials as may hereafter be decided in the capitals of England, Scotland and Ireland; and to offer to erect as a memorial to Mr. Gladstone at Hawarden a building to contain the books of St. Deiniol's Library, which were gathered during his lifetime and placed by his own hands in the structure where they now are."

The Report of the National Trust for Places of Historic Interest states that Joiner's Hall, Salisbury, has been acquired. The sale of the Marquis of Worcester's Monmouthshire estate, it was said, might possibly provide the Society with the opportunity of acquiring Tintern Abbey, a piece of property of national interest. The Society hope, as soon as the necessary arrangements can be made for the transfer, to become the trustees of the site of Driffield Castle and an old columbarium at Garway, near Ross.

A Tomb of a remarkable character has been discovered in the course of excavations at the Eastern Chapel of Peterborough Cathedral. From a figure on it having a roll and a yard measure it is supposed to represent the abbey tailor, but may with as much reason be supposed to be connected with the works.

The Committee on Museums are understood to recommend in connection with the appointment of officials :—(1) That the scheme of special examination already in operation in connection with the Jermyn Street Museum should be extended to South Kensington ; (2) that, following the practice of the British Museum, no examination should be held unless there be a minimum number of candidates ; (3) that no member or paid official of the Science and Art Department should be employed as examiner ; and (4) that the regulation (abolished in 1871) requiring reports upon the qualifications of all new officials to be sent to the Civil Service Commissioners should be re-enacted.

A Firm of surveyors were recently employed in taking some measurements in St. Bride's Church, and having occasion to leave the building for a few moments, deposited their implements on a seat. On their return they found everything had been taken, their incompleted work having to be left until a further supply of instruments could be obtained.

Architect and Contract Reporter.

EDITORIAL NOTICES.

The authors of signed articles and papers read in public must necessarily be held responsible for their contents.

No communication can be inserted unless authenticated by the name and address of the writer—not in every case for publication, but as a guarantee of good faith.

Correspondents are requested to make their communications as brief as possible. The space we can devote to Correspondence will not usually permit our inserting lengthy communications.

TENDERS, ETC.

*** *As great disappointment is frequently expressed at the non-appearance of Contracts Open, Tenders, &c., it is particularly requested that information of this description be forwarded to the Office, 175 Strand, London, W.C., not later than* 2 P.M. *on Thursdays.*

NEW READING CASE.

To Librarians of the Public Libraries and Reading-rooms.—A new handsome Reading Case can be supplied at a nominal charge of 2s., by post 2s. 6d., on early application to the Publisher, 175 Strand, W.C.

For Advertisement Scale, see page xiii.

IMPORTANT NOTICE.

WORKMEN'S COMPENSATION ACT.

In view of the many difficulties which are certain to arise in connection with the law, practice rules and procedure under the above Act, we have added to our staff A VERY EMINENT BARRISTER, who has made the subject a special study, and will be glad to answer in the columns of this paper any questions relating to the complicated matters arising from the provisions of this difficult Act. Our LEGAL ADVISER will further answer any legal question that may be of interest to our readers. All letters must be addressed "LEGAL ADVISER," Office of "The Architect," 175 Strand, London, W.C.

COMPETITIONS OPEN.

GLASGOW.—Aug. 15.—Designs are invited for the exhibition buildings to be erected on sites in the Kelvingrove Park and Bunhouse Ground. A premium of 200*l.* will be awarded to the author of the design considered first in merit, second and third premiums of 150*l.* and 100*l.* respectively. Mr. H. A. Hedley, general manager and secretary, 141 Buchanan Street, Glasgow.

ROTHERHAM.—Plans are invited for proposed extensions of the Baptist schoolroom, Westgate, Rotherham, at a cost of about 600*l.* Mr. A. Crowcroft, Clifton Crescent South, Rotherham.

SALFORD.—Aug. 16.—Designs for three chapels, offices, lodge, entrance gates and boundary walls at proposed cemetery in Langley Road and Agecroft Road, Pendlebury. Premiums of 50*l.*, 30*l.* and 20*l.* respectively. Borough Engineer, Town Hall, Salford.

STOCKHOLM.—Aug. 31.—Designs for railway station Particulars from the Offices of the Consulate, 27 Great Winchester Street, London.

CONTRACTS OPEN.

ACCRINGTON.—July 26.—For excavation and ballasting for sidings, construction of bridges and retaining walls and erection of new engine-shed, for the Lancashire and Yorkshire Railway Company. Mr. C. W. Bayley, secretary, Hunt's Bank, Manchester.

ALDERTON.—July 27.—For erection of Wesleyan chapel. Mr. F. W. Hinton, Alderton.

ALTRINCHAM.—July 25.—For alterations and additions to the hospital, Market Street. Mr. John Macnamara Bancroft, architect, Hale Road, Altrincham.

ANGLESEY.—July 25.—For re-erection of Groeslon inn, Brynsiencyn. Mr. Richard Davies, architect, Bangor.

AYLESBURY.—July 25.—For erection of a block of workshops at the asylum, Stone, near Aylesbury. Mr. R. J. Thomas, county surveyor, County Hall, Aylesbury.

BARNSLEY.—July 27.—For erection of six houses and outbuildings off Dobie Street. Mr. Herbert Crawshaw, architect, 13 Regent Street, Barnsley.

BARNSLEY.—July 25.—For erection of a store and house at Ryhill. Mr. A. B. Linford, architect, Kelvin Cottage, Wombwell.

BELFAST.—For alterations and additions to shops on Albert Bridge Road. Mr. David M. Cooper, architect, 22 Donegall Place, Belfast.

BILLINGSHURST.—July 25.—For erection of a house on the Eastlands Estate. Mr. C. H. Burstow, architect, 6 West Street, Horsham.

BISHOP AUCKLAND.—July 27.—For erection of a billiard-room and conservatory at Redworth Hall. Mr. F. H. Livesey, architect.

BLACKBURN.—July 26.—For erection of infants' school and alterations and additions to the present boys and girls' schools. Messrs. Cheers & Smith, 24 Richmond Terrace, Blackburn.

BLETCHLEY.—Aug. 2.—For erection of two cottages and a shop, with alterations to existing shop, in Albert Street. Mr. A. E. Wade, 1 Albert Street, Bletchley.

BRIGHTON.—For erection of boys and girls' department of St. Mark's schools, Kemp Town. Mr. Joseph Norton, architect, Alliance Chambers, Sheffield.

ELECTRIC NOTES.

THE purchase of the Birmingham Electric-lighting Company, sanctioned by the City Council, is already bearing fruit, as it is in contemplation to light the reference library and the council house by electricity.

THE Paisley electric lighting committee have agreed to recommend the Town Council to make application for power to borrow an additional 25,000*l.* for the purpose of extending the electric-lighting system. If this amount be borrowed, it will bring the sum raised in connection with the electric installation up to 60,000*l.*

THE Palace Theatre maintains its pre-eminently popular position among the variety theatres, thanks to the liberal policy inaugurated by Mr. Morton of excellent quality of entertainment combined with constant change. The present programme, of which the admirable "American Biograph" still forms the *pièce de résistance*, contains numerous turns of interest, prominent among which are those of Marie Dainton, with excellent mimicry after the manner made familiar by Cissy Loftus; Albert Chevalier, who has greatly amplified the histrionic rendering of his songs, the different characterisation employed in "'E can't take a roise out of Oi," "A Fallen Star" and "Our Bazaar" being very marked; Amann, the facial artist and impersonator, among whose admirable impersonations that of the able manager, Mr. Morton, is not the least excellent, and certainly not the least appreciated. Julie Mackey has a capital song anent T. E. Hooley, which is vigorously applauded, and a new one, "The Pebble on the Beach," which has also "caught on;" Saharet, the Australian dancer, is a marvel of agility; Edwin Latell, a new importation, is a very amusing musical clown; and mention must not be omitted of Herbert Campbell. When we add that the Palace is admirably ventilated, it may be inferred that an eminently comfortable as well as amusing evening can be "put in" at that establishment.

BUILDING AND BUILDERS.

THE church of St. Clement's Danes, Strand, was reopened after restoration on Wednesday afternoon.

A NEW Baptist chapel is about to be erected at Walkley, Sheffield.

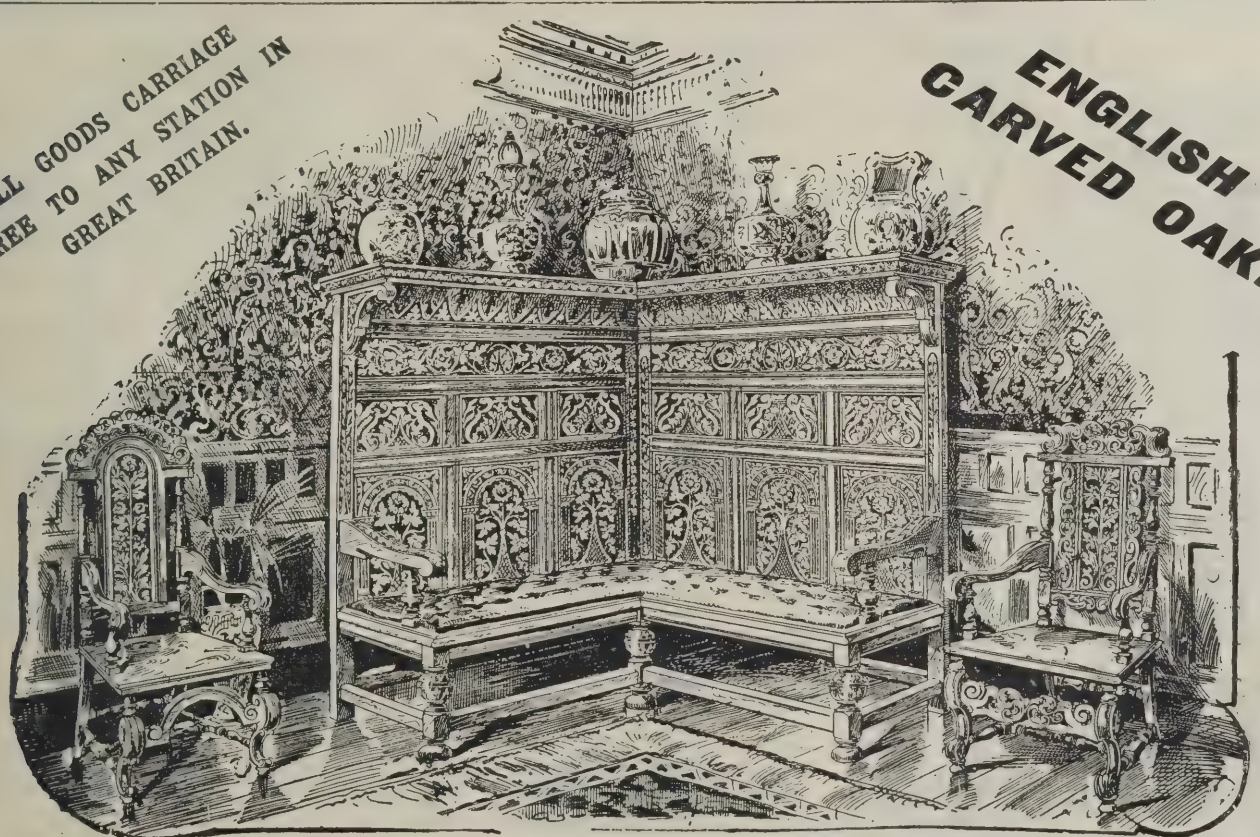
THE foundation-stone of the Herts County Museum, St. Albans, was laid on Wednesday last.

THE congregation of the Hankinson Street United Methodist Free church, Pendleton, have decided to erect new premises, including a chapel and school, at a cost of 1,500*l.*

THE first stone of a monument to be erected in Dublin to the memory of Wolfe Tone and other United Irishmen who were executed in 1798 has been laid on the site of the old Newgate Prison.

AT the weekly meeting of the Salford Board of Guardians it was resolved to purchase about 20 acres of land at Weaste, near the Union Infirmary, as a site for the new workhouse, at a sum not exceeding 14,000*l.*

THE foundation-stone of a new Church institute and club attached to the parish church of St. Marylebone was laid on the 14th inst. The building is to cost about 8,000*l.* This is the fourth building of the kind in the parish.



THE works of the City and South London Railway have made rapid progress lately, and the line will shortly be completed as far as its Moorgate Street station. One tunnel has, in fact, been completed, so that the company's Monument station is already in direct communication with the former.

AS some of the premises now rented by the County Council and occupied by their clerks are scheduled for Government offices, the Council are driven to find more accommodation, and it will be proposed at the next meeting that 25,000*l.* should be spent on the purchase of land and the erection of offices in Warwick Street, Pall Mall, to accommodate seventy clerks. It will be suggested that the Works Department should erect the new offices.

THE Birmingham markets and fairs committee have for some time past been contemplating the removal of the cattle market from Smithfield to Montague Street, in order to give room for the expansion of the wholesale fruit and vegetable market. The committee having consulted the cattle dealers who use the market as to the suitability of Montague Street for the purpose proposed, found that, subject to certain alterations, they were disposed to regard the suggested removal favourably,

and it was decided to recommend the Council to sanction the removal of the market.

CONTRACTS have been entered into by the Government for the erection of three powerful forts at Dover—one between Dover and St. Margaret's Bay and two near the western heights. The forts, which are for the protection of the national harbour, are to be completed, under very heavy penalties, in eighteen months, and were commenced this week. They are to be armed with some 9-inch breechloading wire guns, about 80 tons each, on barbette mountings.

THE Board of Trade have received the following communication *apropos* of the recent dispute in the building trade at Bristol :—

"Guildhall, Small Street, Bristol : July 13, 1898.

"To the Comptroller-General (Commercial, Labour and Statistical Departments), Board of Trade, 7 Whitehall Gardens, London, S.W.

"Sir,—As representing the Bristol Master Builders' Association and the Bristol Operative Federated Societies, we are requested to convey to your Department the heartiest thanks of the employers and employés for the promptitude with which you acceded to our request in the appointment of an arbitrator, and we also desire to convey our warmest thanks to you for appointing so able and impartial a gentleman as Mr. A. A. Hudson to officiate in that capacity. We can assure you that he discharged the duties to the entire satisfaction of both parties, and that his awards were received with great cordiality, and we trust that they will be the means of renewing the friendly relationship between the employers and employés.—We are, sir, your obedient servants,

"N. KRAUSS,
"JOHN CURLE,
"H. J. SPEAR, Secretary."

VARIETIES.

THE Great Eastern Railway Company are issuing a neat and serviceable little *brochure* giving particulars of the increased facilities for visiting Holland, Belgium, Germany, Switzerland, Norway, Denmark and Sweden during the present season, *viâ* the Royal Mail Harwich-Hook of Holland route and the Harwich-Antwerp route to the Continent.

THE beautiful ruin of Ardchattan Priory, on the north side of Loch Etive, Argyllshire, where Robert Bruce held a Parliament, is shortly to be offered for sale by auction in London. It was built by John MacDougal in the thirteenth century, and was burned by Colkitto during Montrose's wars.

THE erection of a monument to Mozart, Haydn and Beethoven, in Berlin, has been entrusted to the celebrated sculptor, Rudolf Siemering, who built the Washington Monument at Philadelphia.

THE Emperor William has conferred the large gold medal for excellence in art on the sculptor Herr Charles van der Stappen, of Brussels, and on Herr Schmitz, architect, of Charlottenburg.

THE first Baptist chapel in Switzerland has been opened. It is at Zurich, and is situated in one of the principal streets of the city. It has seating accommodation for 650, and contains a dwelling for the minister.

LADY HERSCHELL has laid the foundation-stone of a new mission hall in Essex Road, Islington, for the St. John's district. The freehold of the site is a gift, and the cost of erection and equipment of the hall will be about 3,700*l.*

AT a meeting of the museum and school of art committee, Birmingham, held on Monday at the Council House, plans for the branch municipal school of art in the Moseley Road, the erection of which was authorised recently by the City Council, were approved, and it was decided to send out invitations to eight selected firms to tender for the building.

THE Scunthorpe Urban District Council have appointed Messrs. Stevenson & Birstall, of London, engineers for their new gas and water works. The tender of Messrs. Vivian's Boring and Exploration Company, Whitehaven, for sinking the bore the required size and depth has been accepted, the amount being 4,495*l.*

ON the 16th inst. the chimney, 56 yards high, belonging to Grange Mill, Mytholmroyd, which was destroyed by fire, was razed to the ground, in the presence of five or six thousand persons. Mr. Joseph Smith, the well-known Lancashire steeple jack, had the work in hand. Three or four men had been engaged ten or twelve days in cutting out two-thirds of the base, and inserting stout wooden props in its place. This having been completed, a quantity of wood was piled round and saturated with paraffin oil, pitch, &c. These combustibles were set on fire by a number of gentlemen. Mr. Smith continued to feed the fire with paraffin oil for three or four minutes.

In eleven minutes the chimney tumbled over with a tremendous roar, falling in the exact place chosen by Mr. Smith.

FOR the convenience of holiday makers on the Continent cheap tickets will be issued to Brussels, available for eight days, *viâ* Harwich and Antwerp. A through carriage will run from Antwerp to Pepinster for Spa. Passengers leaving London in the evening reach Brussels next morning, after a comfortable night's rest on board the steamer. For visiting The Hague, Amsterdam and other parts of Holland, the Rhine, North and South Germany and Bale for Switzerland, special facilities are offered *viâ* the Great Eastern Railway Company's Royal Mail Harwich-Hook of Holland route, through carriages being run to Amsterdam and Berlin, and through carriages with restaurant cars also run to Cologne and Bale. The General Steam Navigation Company's fast passenger steamers will leave Harwich on July 27 and 30 for Hamburg, returning July 31 and August 3.

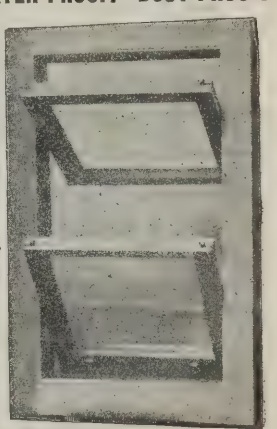
TO those who wish for a pleasant day's outing at a most reasonable outlay the trips by the General Steam Navigation Company's steamers are worth attention. Possibly the best run is by their steamers to Scotland. In the vessels of the company on the Edinburgh route the accommodation allotted to each passenger is unusually spacious and very comfortable. The cuisine is excellent and the charges moderate—comfort rather than an excessive rate of speed being the desideratum the company offers to passengers. The vessels arrive at convenient hours, and at Granton there are frequent trains to Edinburgh, which is a convenient centre from which to start for the Highlands, the Clyde, the Western Islands and all parts of Scotland; but for those who require a shorter trip we can recommend the run to Margate or Ostend, for which tickets are issued at a very low rate.

TRADE NOTES.

IN consequence of Messrs. Goddard, Massey & Warner, Nottingham, declining to proceed with their contract to supply the laundry machinery required at Ruchill Hospital, Glasgow, in terms of the specification, the next lowest offer, that of Messrs. D. & J. Tullis, Kilbowie, amounting to 3,696*l*., has been accepted, and the Nottingham firm have been notified that the Corporation hold them liable for 807*l*., the difference between the amount of their contract and the one which has now been accepted.

THE New Beaumont Park schools, Acton Green, are being warmed and ventilated by means of Shorland's patent Manchester grates.

FOR the new Carlton Hotel, which Messrs. Warings are decorating, Danville asbestic plaster will be used throughout, both for the plain and decorative work.



FOR many years architects and builders have wished that invention had enabled stone to be cut with the same uniformity, economy and expedition which is possible with timber. An attempt was made in the case of marble for mosaics, in which hand labour was almost impossible, but the machines were not adapted for general utility. The long-desired revolution has been accomplished by the Diamond Stone Working Company, Limited. Their machinery is now being recognised as the power which was needed. There is such an opening for it that large capital can be profitably employed in the enterprise. No one can be surprised that the contracts offered and accepted are sufficient to pay a dividend of 6 per cent. for three years on the Preference shares, and there appears to be no exaggeration in the assumption that Ordinary shares will secure a dividend of 20 per cent. It is rarely a business is announced which has such a field prepared for immediate operations, and one, too, from which large profits cannot fail to be realised.

ARTESIAN WELLS.

THE province of Artois, in the north of France, is credited with having given birth to the system of well-boring which bears the name of "artesian." This, however, is scarcely true, for in both the eastern and western hemispheres there are evidences of artesian wells having been sunk at a very early stage of the world's history. They were, of course, known to the Chinese, for among the discoveries which have yet to be made is the modern invention which was not known to that remarkable people.

There is no doubt, however, that in more modern times greater attention was paid to the discovery of subterranean springs in the province of Artois than in any other part of

Europe. Hence the modern title "artesian" wells should seem to be not inappropriate. Indeed, they are very common on the Continent, and in France especially, where that which was long thought to be the largest in existence was bored some fifty years ago. This well is at Grenelle, near Paris, and has a depth of some 1,800 feet, and a diameter of 20 inches at its opening.

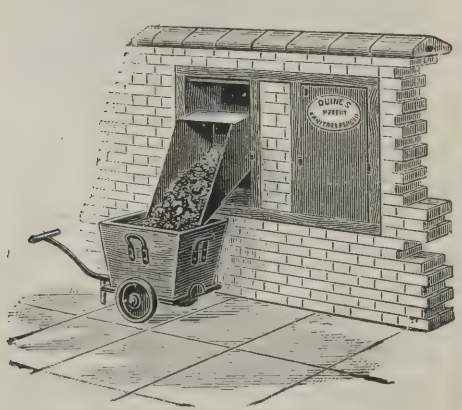
What the engineers of this well would have said to that which was recently bored by Mr. John Thom, of the Canal Works, Patricroft, Manchester, can only be surmised. This well has a diameter at the orifice of 7 feet, and is one of the largest—if not the largest—in the United Kingdom. This, however, is but one of the many large and important well-borings which Mr. Thom has carried out. For mining, manufacturing, brewing, dyeing, and indeed every other purpose for which water on a large scale is required, wells have been satisfactorily sunk by Mr. Thom, and this not only in every part of the United Kingdom, but in distant parts of the world. In the mines of Spain, as well as in those more recently developed in South Africa, on the rock of Gibraltar, and even as far off as Australasia—in these and other parts are Mr. Thom and his wells known.

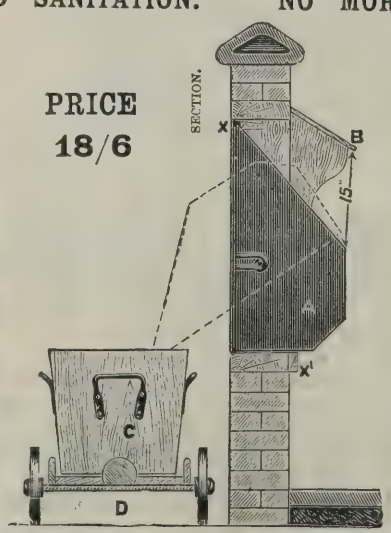
Nor is this surprising, for not only is an artesian well the cheapest and best means of obtaining a large supply of water, but Mr. Thom has made well-boring his special study, and the invention and manufacture of the necessary tools and appliances his special business, and therefore those of our readers who may have occasion to advise or adopt an artesian well could not do better than place themselves in communication with him.

RAILWAY EXTENSION TO THE NORTH CORNWALL COAST.

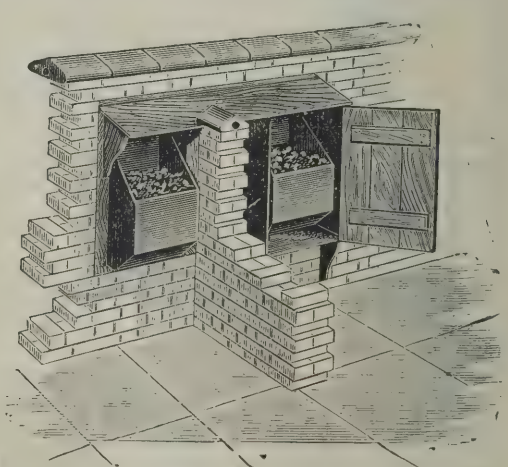
IN the course of a few days the system of the London and South-Western Railway will be extended to Bude, on the romantic and picturesque coast of North Cornwall. The new line is a continuation of the branch railway from Okehampton to Holsworthy, the distance from Holsworthy to Bude being 10 miles 3 furlongs. Immediately after leaving Holsworthy the line crosses the Deer Valley, over which it is carried by a lofty viaduct of nine arches, each of 50 feet span, the height from the permanent way to the valley being 89 feet. There being no suitable building material in the district, it was decided to construct the viaduct wholly of concrete, and this has been done with conspicuous success, the result being a handsome structure which is the first of the kind in the country.

The piers and arches were built with blocks of concrete, and the foundations and abutments of concrete in mass, the whole of the material being made with broken stone found in the neighbourhood, mixed with inland sand brought from Plymouth and Bideford. At Woolston there is a second viaduct of similar design, but this is not more than 60 feet high, and the two represent a successful application of concrete which has never before been adopted.





There is only one intermediate station, and this is placed at Whitstone, about midway between Holsworthy and Bude. An excellent position has been chosen for the site of the terminus in Bude, namely, quite close to the junction of the Bude and Stratton main roads, half a mile from the centre of the former town. The station is a handsome structure of red brick, relieved by white quoins. Here, as also at Holsworthy and Whitstone, ample platform accommodation has been provided, and in addition to cloak and retiring-rooms there is to be at Bude an excellent refreshment buffet.



A branch line for the purposes of goods traffic has been laid to the basin of the Bude canal, and another branch may eventually be carried to Marhamchurch, within easy reach of the magnificent Widemouth Bay, which would convert it into a fashionable bathing-place, the stretch of sand on the shore being one of the finest in North Cornwall.

The railway from Holsworthy to Bude consists in the first instance of a single pair of rails, but land has been taken and viaducts have been constructed so as to permit of the introduction of a second set of metals, and the directors of the South-Western Company are prepared to double the line whenever the local requirements may necessitate larger provision for the traffic. The ruling gradient is 1 in 73, which for North Cornwall is comparatively good, and all the curves permit of fast running. Tyer's Tablet System will be used in working while the line remains single, and as the heaviest type of the South-Western permanent way has been employed in construction, high speeds can be maintained with perfect confidence.

Messrs. John Aird & Son are the contractors, and their work has been completed within eighteen months, thanks in a very large degree to the active and constant exertions of Mr. W. Granger, the local representative of the firm. The line was

designed by Mr. W. R. Galbraith, the consulting engineer of the London and South-Western Railway Company, and constructed under his personal supervision and that of his partner, Mr. R. F. Church, the resident engineer being Mr. E. Connal.

BERLIN PAVEMENTS.

IT appears from some statistics furnished by the United States Consul at Berlin respecting the carriage pavements of that city, that wood pavement does not find much favour there. The area of pavements is 6,500,405 square yards, and of this area a little less than 74 per cent. has stone pavements, about 25 per cent. asphalte, and a fraction over 1 per cent. wood. The Consul states that the proportion of asphalte is steadily increasing. The soil consists of coarse gritty sand, forming apparently an excellent foundation for the heavy 8-inch layer of gravel and cement, over which the 2-inch covering of asphalte is spread.

AUSTRALIAN FACTORY LEGISLATION.

IN New South Wales all industrial establishments in which steam or other mechanical power is not used, and employing four persons or upwards, also every room or workshop where two or more Chinese are employed, situated within the Sydney and surrounding district, embracing an area of 500 square miles, have been brought under the operation of a Factory and Workshops Act, passed in 1896, with a view to regulating the hours of employment for women and children and enforcing sanitary conditions where required. Three inspectors, two male and one female, are employed, and the report of the first year's operations is instructive and interesting. At the close of 1897 the number of registered industrial establishments within the area mentioned was 1,673; but there are many which have yet to be registered. In a large number of these the prevailing cleanliness and completeness are not to be excelled in older countries; in others the conditions are such as to necessitate a strict enforcement of the law. The Act requires all machinery to be fenced where dangerous, but the readiness with which employers regarded the necessity for something of the kind has prevented any friction. In every instance the factory inspectors were content to pass guards that substantially effected their object, although they might be somewhat rough in appearance. It was felt that employers ought not to be put to a larger outlay than was absolutely necessary to effectually secure their hands from the risk of accident. The utility of the guard was more thought of than its appearance. Despite this fact, many occupiers have gone to considerable expense in fitting neat and well-furnished guards to their machinery. In some places dining-rooms for the use of the employed have been provided; but in others, in view of the possible heavy cost to employers, their establishment is not being pressed at present.

FIREPROOF CONSTRUCTION IN AMERICA.*

THE closing years of the nineteenth century will, no doubt, be memorable in history for the rapid and remarkable developments in building construction. The empirical and wasteful methods of the past have been entirely revolutionised, and economy—in space, in time and in material—is the dominating feature of every design.

The modern high building with its steel skeleton frame is essentially the creation of the civil engineer. It was made feasible by the practical solution of many difficult and intricate problems, among which is that of fire-resisting or so-called "fireproof" construction.

The inefficiency of the ordinary fire-extinguishing apparatus at heights exceeding 125 feet made it necessary to employ incombustible materials in high buildings. These materials are used for the walls, floors and partitions in such a manner and in such quantities as to confine a fire from any cause to the apartment in which it originates, and thus prevent the destruction of the entire building. Owing to the fact that the strength of iron and steel is greatly diminished by heat, the problem of fireproofing a building is further complicated by the necessity of suitably protecting the structural ironwork.

Until recent years fireproofing methods were based solely upon theory and were largely in the experimental stage. Numerous elaborate tests made during the last three years on a scale sufficiently large to represent practical conditions were witnessed by the writer, and other similar tests were also made under his supervision. These have proved very instructive and have thrown considerable light upon a subject concerning which there has been hitherto an utter lack of precise know-

ledge. The general facts and conclusions, as recited in this paper, represent some of the results of the writer's personal research and observation.

In the highest class of fireproof buildings all woodwork and other combustible material is carefully excluded. The interior finish in such buildings is wrought in stone, cement, plaster, metal or glass. In many buildings, however, the question of cost frequently precludes the use of the best or strictly non-combustible material, and until an equally low-priced substitute can be found more or less wood will be used for the interior finish. Although the use of wood or other combustible material is very undesirable in a fireproof building, it has been proved many times by actual conflagrations that it is entirely possible to employ fireproof materials in such a manner that the combustible finish and contents of an apartment may be consumed without causing other damage.

Fireproof buildings in which no steel or iron enters into the construction are so massive as to be monumental in character and too rare to receive further consideration. The exterior walls of steel skeleton fireproof buildings are usually constructed of brick or stone, but the floors and partitions, on account of special conditions, are built of a greater variety of materials. What follows will therefore relate more particularly to the fireproof floor construction between the steel beams and the protection of the steel skeleton frame.

Practical and efficient fireproof construction depends primarily upon, first, suitable materials; and second, correct methods or systems of employing such materials.

In order that a material may be fireproof in the broad sense in which the term is now used, it is not only necessary that it shall successfully withstand the highest temperatures that are obtained in actual conflagrations (2,000 deg to 2,300 deg. Fahr.), but it must also retain its strength and resist disintegration when suddenly cooled by a stream from a regulation fire-engine. In addition to these requirements, it is desirable that the material should be inexpensive, light, a good non-conductor of heat, and that it shall not discolour plaster.

No material has yet been discovered that fulfils all these requirements perfectly. Some of the materials in use at the present time, however, meet the requirements to such a degree as to make them practicable for fireproofing purposes. A few of these will be enumerated in the order of their merit, omitting such materials as are made by patented or secret processes.

First, Cinder Concrete.—In the elaborate series of fire and water tests conducted by the New York City Building and Fire Departments in 1896 and 1897 "cinder" concrete developed the highest fire and water-resisting efficiency of the various materials tested. The concrete consisted of one part of high-grade Portland cement to two parts of sand and five parts of cinder (the residue of anthracite coal consumed in boilers). Cinder concrete is, however, quite heavy, weighing 75 to 90 lbs. per cubic foot, depending upon manipulation, &c., and ranks below the plaster of Paris compositions as a non-conductor of heat.

Second, Burnt Clay Products.—These have been used for fireproofing purposes for many years. They consist of ordinary brick and hollow brick made of hard burnt clay, porous terra-cotta, terra-cotta lumber, &c. None of these materials as offered in the market are capable of withstanding as high temperatures as cinder concrete. Ordinary brick are exceedingly heavy, weighing 130 lbs. per cubic foot; the hollow bricks are lighter, but when highly heated and suddenly cooled by a fire stream, the under surfaces are disintegrated, exposing the cellular surfaces.

Third, Plaster of Paris Compositions.—Plaster of Paris is a well-known non-conductor of heat. When wood shavings are incorporated in it the composition is very light, weighing about 42 lbs. per cubic foot. Broken brick, cinder, &c., is sometimes used instead of wood shavings, but the resulting concretes are much heavier. All plaster of Paris compositions absorb moisture rapidly and dry slowly. They soften under the fire stream and are rapidly disintegrated by it.

Fourth, Stone Concrete.—Ordinary stone concrete is even heavier than common brick, and weighs about 140 lbs. per cubic foot. With sandstone aggregates it is capable of withstanding as high temperatures as the burnt-clay products, but if highly heated and suddenly cooled with a fire stream the material disintegrates on the surfaces so cooled, the disintegration continuing until a certain lower temperature is reached, which temperature varies with the character of the concrete.

Fireproof floors between the steel beams may be divided into three general classes:—1. Monolithic constructions. 2. Constructions consisting of assembled parts. 3. Constructions with light metal constituents.

First, Monolith Constructions.—These are erected in the form of segmental arches or flat slabs, between or over the steel floor-beams. The material is generally placed in position while in a plastic state on temporary wood or permanent metal centring, and allowed to "set" or harden. In the monolithic

constructions the thrust is largely eliminated, and there is no liability of settling or displacement of parts.

Second, Constructions Consisting of Assembled Parts.—These are usually built in the form of segmental or flat arches. On account of the thrust which is always present in constructions of this character, the beams should be well tied together at intervals not exceeding eight times their depth. Great care should also be exercised in erecting the arches so as to make perfect joints and give the material full bearing over the entire surface of the joints. Special precautions should be taken in the case of "end construction" hollow tile, in which the cellular spaces and webs run in a transverse direction to the beams. The blocks should be accurately set so that adjacent ribs or webs come opposite each other and form a continuous rib or web from beam to beam, or skew-back to skew-back. With imperfect joints arches of this class will settle, causing cracks in mosaic or other expensive floor finish, and in the plastered ceilings if the plaster is applied directly to the under side of the arch. Wood centring is generally necessary to support the work until the mortar sets. As the thrust increases very rapidly with the span, the rise remaining the same, wide spacing of beams should be avoided. In arches adjacent to exterior walls, the tie rods should be carefully protected so as to prevent thrust against the walls in case of fire.

(*To be concluded.*)

PROPOSED WIDENING OF HOLBORN.

A PROPOSAL will shortly be made to the London County Council by its improvements committee for the widening of the portion of High Holborn between Southampton Row and Southampton Street. High Holborn at the spot in question is at present 55 feet wide, and it is proposed to increase this to 70 feet. The buildings fronting the portion of the street to be widened are now in course of demolition, and the freeholder and lessee have expressed their willingness to treat with the Council for the acquisition of the necessary land. The officers of the Council estimate the net cost of the improvement, including the necessary paving and other works, at 56,000*l.* The committee think the present opportunity for carrying out the work is a very favourable one, and that the improvement is desirable as a complement to the widening of Southampton Row now being undertaken by the Council. They point out that High Holborn, like the Strand, is and must continue to be one of the greatest east and west thoroughfares in London. The traffic at Southampton Row is frequently blocked, and they think the Council should readily avail itself of the opportunity of increasing the width of the road at such comparatively small cost. If this opportunity is not seized they state that new buildings will at once be erected, and the cost of carrying out the work in the future will be prohibitive.

ADVERTISEMENT HOARDINGS.

AT the meeting of the Metropolitan Asylums Board on Saturday, the 16th inst., the general purposes committee brought up a report containing a proposal to the effect that in future the letting of hoardings for advertisement purposes should be determined by the board. Mr. W. M. Acworth said he considered it a scandal that a body like the Metropolitan Asylums Board should, for the sake of a few hundreds of pounds, disfigure the Thames Embankment, on which the chief offices of the board were being erected, with abominable advertisements. If they walked down Whitehall, he said, they would find a large hoarding around some buildings which were being removed, but the Government had refused to allow the hoarding to be run up 20 feet or 30 feet simply in order that the space might be disfigured by huge advertisements. How, he asked, would the House of Commons look if when any portion of it was being repaired the hoarding was covered with advertisements of somebody's soap and whisky? He believed that many individual members of the board would rather pay an extra halfpenny on the rates than be a party to the disfigurement of a place like the Embankment. He moved as an amendment that, in the opinion of the board, hoardings around buildings should not be let for advertisement purposes. The amendment having been seconded, Mr. A. C. Scovell remarked that it seemed quite uncalled for. He was aware that there were a few people in London who were so æsthetic that they could not bear to look upon posters. It was quite possible that the day might come when advertisement posters would be suppressed by law, but for his part he thought the advertisement posters of the present day did a great deal more good than harm, as they gave instruction and amusement to a vast number of people whose means of instruction and amusement were very limited indeed. Mr. Scovell said he protested against the board posing before the public as a crusader against advertise-

ment posters in the Metropolis. The amendment on being voted upon was lost by a large majority. The recommendation of the committee was then adopted.

THE SANITARY INSTITUTE.

THE following questions were proposed to the candidates for the certificate of the Sanitary Institute at the examination in Cardiff on July 8 and 9 :—

Define motion, velocity, force, matter and pressure.

What is the action of waters of varying compositions on lead pipes? What is the best method of dealing with the distribution of water known to take up lead? What quantity of lead in water is considered objectionable? and how would you ascertain its presence?

Define the expression "degrees of hardness" as applied to potable waters. How would you estimate the hardness of water?

What considerations would govern your selection of a site for an impounding reservoir in a mountainous district? How would you proceed to ascertain the quantity of water available for supply?

What are the constituents of Portland cement, and from what does it derive its hydraulicity? What is the setting of the cement due to? How would you proceed to test a sample of cement?

Under what conditions is carbon-monoxide gas sometimes found in the air of inhabited places? What is known about the physiological effects of this gas on human beings?

What process would you recommend for dealing with the sewage from an ordinary town previous to its discharge into a brook, the flow of which is twenty times that of the dry weather flow of the sewage?

Give the substance of the London County Council Bye-Laws in reference to the construction of new water-closets. How far do the same by-laws apply to the alteration of existing water-closets?

What head of water is sufficient for testing stoneware socket-jointed pipes, and what time should elapse between making the joint (Portland cement) and applying the test?

Give detailed directions for disinfecting the surfaces of a room with an area of 2,500 cubic feet by means of—(*a*) A liquid disinfectant ; (*b*) a gaseous disinfectant.

Describe the method you would use and the instruments you would employ if asked to make a complete and detailed report upon an ordinary house as to—(*a*) The ventilation ; (*b*) the drainage ; (*c*) the sanitary appliances ; (*d*) the general sanitary condition.

State the relative advantages and disadvantages of a combined and separate system of dealing with the sewage and rainfall of an urban district.

What statutory provisions relating to an adequate pure supply of water to premises are in force—(*a*) Under the Public Health Act, 1875? (*b*) Under the Public Health (London) Act, 1891?

SOCIETY OF ENGINEERS.

A PARTY of the members of the Society of Engineers on Wednesday, July 13, visited the L. B. and S. C. Ry. locomotive works at Brighton, the Brighton Marine Palace and Pier Works, Volk's Electric Railway, the Brighton and Rottingdean Seashore Electric Tramroad. Among those present were Mr. W. Worby Beaumont, president ; Mr. A. T. Walmisley, past president ; Messrs. J. C. Fell and Charles Mason, vice-presidents ; Messrs. George Burt, D. B. Butler, Percy Griffith and R. St. George Moore, members of Council ; F. W. Barclay, S. O. Cowper-Coles, T. F. Craddock, John Jones, N. Harker, Fred. Hovenden, E. Hulburd, R. J. G. Read, J. Waddington, W. G. Wales and Weatherburn, and Mr. G. A. Pryce Cuxson, secretary.

The visitors to the railway works, after arriving at the passenger station, passed along the east or "Kemp Town" platform to the entrance to the works, which is close to the north end of the platform. They then inspected the iron foundry, saw mills, carriage fitting and wheel shops, smith's shop, turnery and brass foundry, returning through the erecting shop, boiler shop and carriage building shop. Crossing the line to the west side, they passed through the waggon building and repairing shop to the trimming and paint shops, after which they returned viâ the running shed to the west or "Portsmouth departure" platform.

About 2,000 men are employed in these works, mainly for repairing and renewing rolling stock, which now consists of 461 engines, 2,970 carriages and 8,693 waggons. New stock is built here at the rate of about twenty engines, 100 carriages and upwards of 400 waggons per annum. Repairs to the machinery of the company's steamboats are also effected here, as well

PATENT

VULCANITE ROOFING.

Since the introduction of the patent Vulcanite Roofing into this country it has been adopted by a great number of leading architects for Public and Private Buildings, Hotels, Schools, Hospitals, Theatres, Mills, Warehouses, Breweries, Shops, Villas, Dwelling-houses, &c.

The temperature of the rooms immediately beneath the roof is more even in winter and summer than under any other roof. When properly laid repairs are never required, and all roofs are guaranteed. The roof-surface can be used as a garden, or for any other purpose. The cost of construction is less than even for a slate or tiled roof.

SHEET ASPHALTE for DAMP-COURSE, WATERPROOFING VAULTS, BRIDGES, TUNNELS, &c., is manufactured ready for use in lengths of 40 feet, and any width up to 40 inches, being more convenient than the usual damp-course slabs, and saving laps. Price lower and quality much superior to any similar article in the market.

SHEET ASPHALTE for ROOFING SHEDS, LIGHT BUILDINGS, &c., and for SARKING under slates or tiles, manufactured in five different qualities and in rolls of 15 superficial yards. It is easily laid, very inexpensive, much superior to felt roofing, and requires no annual coating.

Full particulars, Catalogues, Detail Sketches, Estimates, re Vulcanite Roofing ; Samples, Prices, &c. re Sheet Asphalte, free.

THE PATENT VULCANITE ROOFING & ASPHALTE CO., LTD.,

28 VICTORIA STREET, WESTMINSTER, LONDON, S.W.

Inquiries from the North of England, Scotland, and Ireland, please address to Laganvale, Belfast.

Agents wanted in all districts where not yet represented for laying of Vulcanite Roofs and Sale of Sheet Asphalte.

as at the special workshop at Newhaven; also repairs to the hydraulic machinery in connection with the various goods depôts, together with work in connection with the numerous water supplies and pumping stations for supplying the line with water. Since the appointment of Mr. R. J. Billinton there has been an installation of hydraulic machinery in the boiler shop, which latter has also been enlarged, and the roof raised for receiving the 12-ton overhead travelling cranes driven by rope. The erecting shop has also been enlarged, and the overhead cranes, instead of being driven by shafting, have been altered and driven by rope, this work being carried out by Messrs. Craven Bros., Manchester.

Since the last visit of the Society of Engineers several new tools have been placed in the works for decreasing the cost of manufacture, and all of them have proved most efficient. The electric light has also been added to the station; this installation is worked from the shops, and the railway company is now about to lay down hydraulic machinery and cranes for working the enlarged goods yard. A large portion of the carriage stock is now lighted with compressed oil gas, and works have been erected for making and compressing this oil gas near the north end of the erecting shop.

The next visit was to the new pier, which is being constructed by Mr. John Howard, Westminster, from the designs and under the superintendence of Mr. R. St. George Moore, M.I.C.E., of Westminster. This pier is practically opposite the entrance to the Aquarium and about 150 yards west of the site of the Chain Pier, whose successor it really is, as the company had purchased the old Chain Pier and entered into an agreement to pull it down on the completion of the new pier. It will, when completed, be 1,750 feet, or practically one-third of a mile long—and 45 feet wide at the narrowest point. There will be sufficient water at the landing-stage to enable Channel steamers to come alongside at all states of the tide. It is also proposed to erect on the pier a handsome pavilion containing a concert-hall, dining and refreshment-rooms, shelter-seats and retiring-rooms. The steam machinery for screwing the piles is also worthy of note, being capable of screwing a 12-inch pile with a 2 feet 6-inch screw-blade 10 feet into the ground in an hour and a half. Mr. W. Collins, the foreman in charge of the work, has succeeded with this machinery in erecting 60 feet of the pier in seven days.

Volk's Electric Railway was also inspected. This railway is well known as the pioneer electric railway in the United Kingdom, having been opened before the Giant's Causeway Electric Railway. The line is three-quarters of a mile long, is worked on the third rail system, and has carried more than the whole population of the county of London.

The Brighton and Rottingdean seashore electric tramroad is one of the latest and most peculiar applications of electric traction. The line is situated on the foreshore entirely between high and low water, and extends from the Paston Place groyne, within the borough of Brighton, to Rottingdean—a distance of 2 miles 7 furlongs. At high-water of spring tides, at the deepest portion of the line, the rail-level is 15 feet below water-level.

The permanent way consists of four lines of 52 lbs. steel flange rails laid in pairs to a gauge of 2 feet 8½ inches, and to a total gauge between the outer rails of 18 feet. The sleepers of ordinary railway practice are substituted by concrete blocks and large cast-iron chairs, according to the nature of the ground. The car is carried on sixteen 33-inch wheels in four bogeys, two of which occupy each a line of road, and are held in position by a strong steel framing. On each bogey stands a main steel tube column, from which spring the arched girders supporting the deck, which is 25 feet above rail level, and is 46 feet long by 22 feet wide. There is a deck-house 25 feet long and 12 feet wide; when fully loaded it weighs about 50 tons. Mr. Magnus Volk, M.I.E.E., of Brighton, and Mr. R. St. George Moore, M.I.C.E., of Westminster, were jointly responsible for these works.

GEORGE WOOLISCROFT & SON, LIMITED, v. KIRK & RANDALL.

THIS motion was heard before Mr. Henning, Q.C., one of the official referees, from June 26 to July 2. It was an action brought by George Wooliscroft & Son, Limited, tile manufacturers, of Hanley, Staffs, against Messrs. Kirk & Randall, builders and contractors, of Woolwich, to recover the sum of 332*l.* 14*s.* 3*d.*, the balance alleged to be due to them in connection with the tiling of the Cleveland Road Board schools Ilford, as sub-contractors of the defendants, who were the building contractors. On the matter coming before the Master in Chambers, he gave leave to the plaintiffs to sign judgment against the defendants for the amount claimed, but stayed execution until the trial of a counterclaim set up by the defendants against the plaintiffs for a greater amount than that claimed by the plaintiffs; and it was this

counterclaim which has lately engaged the attention of the official referee. The contention of the defendants was to the effect that the plaintiffs had been dilatory and negligent in the execution and completion of their tiling, and so had caused damage and loss to the defendants by putting them in arrear and behindhand with their own work, and therefore preventing them from completing the job as expeditiously as they might otherwise have done, and they therefore claimed the sum of 417*l.* 7*s.* 1*d.*, of which 339*l.* 1*s.* 7*d.* was for damages, from the plaintiffs. The balance of 78*l.* 5*s.* 6*d.* was claimed by the defendants as a discount, which they contended they were entitled to deduct from the plaintiffs' claim; but the official referee held there was no agreement to allow it, although the plaintiffs had offered to do so if the account had been amicably settled. On the question of damages, the plaintiffs' counsel stated their case was that, by the terms of the contract the plaintiffs were only bound to complete their work within three weeks of the completion of the "floating" of each floor of the building, and which he submitted the plaintiffs had duly complied with. The plaintiffs also alleged delay on the part of the defendants and their sub-contractors in their work, which would have prevented the building being completed any earlier than it was even if the plaintiffs had finished the tiling earlier; and they also alleged that in the course of the building the size and shape of the tiles had been altered, but this the defendants denied. Evidence in support of the defendants' case was given by Mr. Randall, Mr. C. J. Dawson (the architect for the building), Mr. Henshaw and Mr. May, and at the conclusion of their evidence the plaintiffs' counsel submitted to the learned referee that no case was made out by the defendants. In reply to the official referee the plaintiffs' counsel said that, in order to save further costs by prolonging the inquiry and calling witnesses, he would be willing, without admitting liability, to give the defendants 32*l.* on their counterclaim, upon the basis that it was agreed by the defendants that the question of costs was left to the discretion of the official referee. This offer the defendants' counsel accepted, and accordingly judgment by consent was given for the defendants on the counterclaim. On the question of costs, the official referee said he should not order the plaintiffs to pay any costs of the counterclaim, as he thought the counterclaim preposterous. It ought never to have been set up, and it could not hold water. The plaintiffs' counsel, however, asked further that the defendants should be ordered to pay the plaintiffs' costs of the reference, contending that the counterclaim should never have been set up, and he called attention to the fact that before the counterclaim was delivered, the plaintiffs' solicitor had, in order to avoid the cost of the reference, offered to reduce the amount of the plaintiffs' judgment by a greater sum than the 32*l.* 10*s.* 8*d.*, which the defendants had then accepted, they would have had to pay the plaintiffs a lesser sum than was now recoverable by the plaintiffs. This application was resisted by the defendants' counsel. Ultimately the official referee decided the question of costs in favour of plaintiffs, and ordered the defendants Kirk & Randall to pay the plaintiffs, George Wooliscroft & Son, Limited, the costs of the reference and all the costs of the counterclaim.

Mr. Frank Gover, instructed by Mr. W. Saunders Fiske, of 10 Norfolk Street, Strand, W.C., appeared for the plaintiffs, and Mr. Hudson, instructed by Messrs. Mackrell & Co., of 21 Cannon Street, E.C., appeared for the defendants.

PATENTS.

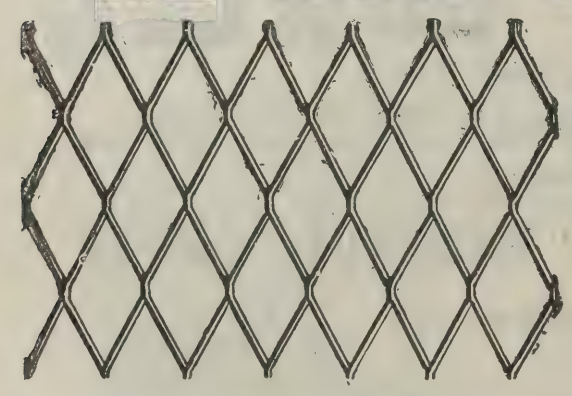
[*This List of Patents is compiled specially for this Journal by Mr. G. H. Rayner, of the firm of Rayner & Co., Consulting Patent Agents, 37 Chancery Lane, London, W.C., from whom all particulars and information relating to Patents may be had gratuitously.*]

Applications for Patents.

14657. William Oates, for "Improvements in and appertaining to waste water-closets."

14880. James Scott, for "Improvements relating to ventilating, disinfecting, heating and cooling structures."

15103. John Hollis and Thomas Hollis, for "Improvements in wood-block flooring."



16027. Grayson, for "Bricks."

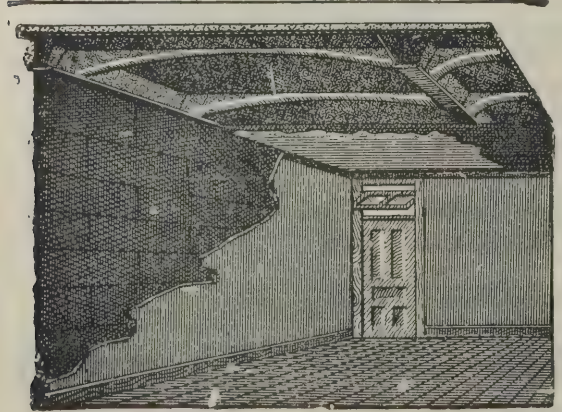
25734. Clark, for "Apparatus for moulding or forming bricks, tiles, earthenware pipes or the like."

4273. Sheppard, for "Smoke-preventer, being method of curing smoky chimneys."

To Inventors.—Patents for Inventions, Trade-marks and Designs secured; every assistance given to inventors. Specialists in Building matters. Information free.—Messrs. Rayner & Co., Patent Agents, 37 Chancery Lane, London, W.C.

THE NEW EXPANDED METAL

Meshes from ⅛th in. to 6 in. wide. Strands from 24 B.W.G. to $\frac{3}{16}$th in. thickness of steel.



FOR BUILDING CONSTRUCTION, as supplied to a large number of important Buildings, both Public and Private, in this country and abroad.

FOR SOLID PLASTER PARTITIONS, 2 inches thick, with Expanded Metal Lathing. Fireproof, vermin-proof and practically sound-proof.

FOR FIREPROOF LATHING, for attaching to wooden joists and studs, for walls and ceilings, also for suspended ceilings, ornamental mouldings, encasing columns, girders, &c.—no cracking or falling away of plaster to be feared.

FOR CONCRETE FLOORS WITH EXPANDED METAL.—The remarkable results and advantages of these will be better understood by perusal of the Report hereinafter referred to.

FOR EXTERIOR WALLS OF BUILDINGS.—Cement applied to Expanded Metal is not liable to crack or fall away through changes of temperature.

FOR FENCING, TREE GUARDS, WINDOW GUARDS, as supplied to the Royal Parks, leading Railway Companies and landed Estates throughout the Kingdom.

ORNAMENTAL. STRONG. CHEAP.

OTHER USES FOR EXPANDED METAL.—These are innumerable. It can be used wherever lattice-work is required, from a letter-rack to a lift-shaft, for garden bordering and archways. Is highly ornamental and exceedingly durable, having no joints to rust away.

Being expanded by rapid machinery it is considerably cheaper, strength for strength, than any other description of metal lattice-work.

BRASS, ALUMINIUM, or any other ductile metal can be expanded, and the effect is very pleasing, and here again the absence of joints gives great durability to the metal, and its rapidity of manufacture allows of very low prices.

CATALOGUES AND PRICE LISTS can be obtained on application. Also copy of a REPORT by an EMINENT FIRM of ENGINEERS on the use of EXPANDED METAL IN CONCRETE.

The Architect.

THE WEEK.

THE following strange story about the procedure adopted to discover an architect who would be qualified to design the proposed Government Offices is printed in the last *Journal* of the Royal Institute of British Architects :—"The selection of Mr. J. M. BRYDON [*F*] and Mr. WILLIAM YOUNG [*F.*] as the architects to be entrusted with the preparation of plans and drawings for the new Government Offices has relieved the Council of the duty of silence as to the relations between Her Majesty's Government and themselves. It has been considered desirable that a short account of these relations should be published for the information of members. In January a letter was received from the Secretary of Her Majesty's Office of Works requesting the Council of the Institute to suggest a 'limited list of architects of taste, skill and efficiency in Classical design' who could carry out the works in question. The Council were also requested, while submitting the list of architects, to furnish the Government with a list of the principal buildings erected by each, together with photographs and illustrations. At the same time the President received a semi-official communication requesting that the Council would regard all proceedings as strictly confidential. At the next meeting of the Council a committee, consisting of the President, a vice-president, Mr. JAMES BROOKS, Mr. ASTON WEBB and Mr. CAMPBELL DOUGLAS, was appointed to draw up and submit to the Council a list of names from which final selection could be made. Meanwhile, a guardedly expressed letter was addressed to each of the allied societies requesting each to nominate two Classic architects in their district, and forward to the Council photographs of their works. At the first meeting of the committee a selection was made among the provincial architects so nominated, and a list of London architects was drawn up, who were to be invited to send in photographs of one or two of their works executed in the Classic style. With a few notable exceptions the London architects responded to the invitation. A second meeting of the committee was held, the photographs were inspected, and out of the twenty-two names before them twelve were chosen by ballot to recommend to the Council. At a meeting of Council held on March 7, two names were added to the committee's list, and a ballot was taken for the selection of eight names. These were submitted, in alphabetical order, to the Government. A day or two later it was notified to the President that the Government would be glad to have one or two extra names, and that the matter was urgent. Accordingly the three names next on the voting list, which were bracketed together as having obtained one less vote than the last of the eight, were sent in. In each case the photographs submitted to the Council were forwarded to the Government."

BUILDING is a sure gauge of public security, and when we find in Johannesburg an extraordinary decline in the number of new works, it is evident there can be little confidence in the Government. In 1894 there were 967 new buildings, in 1895 the number was 1,978, the following year the number was 1,964, but in 1897 there were only 784 new buildings The alterations and additions have followed a similar rate of decline, the numbers being for the same period 269, 560, 527 and 274. The information is derived from the report of the town engineer, Mr. CHARLES ABURROW. What appears to be no less ominous is the indifference of the authorities as well as the inhabitants to the law. Draft regulations were drawn up and submitted respecting fire walls, theatres, balconies, staircases, &c., but although urgently required, the Government will not take the trouble to pass them. During the year 1897 there were no less than 997 notices sent out of contravention of building bylaws. In several instances buildings were erected in public thoroughfares. During the year 1897 about 5¼ miles of gas mains and branches were laid, the total length of mains being about 25 miles. The average price of gas was 18*s.* 8¾*d.* per 1,000 cubic feet. The total length of streets containing electric mains is about 25½ miles, representing 87 miles of wire. There are approximately 21,000 lamps connected to the mains. The price per unit was a fraction under 1*s.* 5*d.* Owing to the large number of indigent people who were unable to obtain employment, the engineer was instructed to engage white men instead of coolies for stone-breaking at the same rate of pay, but after a few days' trial it was found that the men were very dissatisfied with the arrangements and refused to proceed with the work unless they received from 35*s.* to 2*l.* per week. The employment then ceased.

IT is to be hoped that before the crowds arrive to visit the Paris Exhibition of 1900 some of the scaffolding will be removed from the public buildings in that city. There may of course be many builders and students of architecture to whom French scaffolding will be interesting. It is usually constructed of massive timbers united with great care. In fact a scaffolding had need to be substantial in Paris, for apparently nobody can tell how long it will have to remain The Madeleine wants some reparation, but it is anticipated that a forest of square timber will envelop the building in order that some of the Corinthian capitals may be made secure. We suppose the authorities consider there is some constructive virtue in the pieces which passes to the masonry, for it often happens that when set up the scaffolding is not used to support platforms for builders. The interesting church of the Sorbonne has been concealed by timber for over a couple of years, but as a mason is rarely seen upon it the advantages of so costly an example of timber construction are not evident.

THE consternation at the decision of the French Minister of Finances to sell a part of Mont Saint-Michel as a site for a casino will not be confined to French archæologists. Wherever picturesque beauty is admired, the group of buildings surmounting the rock is recognised as one of the works which would lose character by any novel feature in their vicinity. There seems, however, to be an epidemic among the present Government for selling the relics of ancient France. The Minister of War has also arranged to dispose of the fortifications of Aigues-Mortes, which in their way are no less remarkable than the monastic buildings. The Commission of Historic Monuments is not allowing the proposal to pass unnoticed. On Friday last a resolution was passed asking that the control of the fortifications in question should be made over to the Department of Fine Arts, in which case they would be preserved by the Commission. They have also unanimously protested against the sale of any part of Mont Saint-Michel. But as money is now much needed for armaments, it is feared the ministers will have their way.

THE three gorgeously sculptured crosses of Monasterboice, County Louth, are the finest in Ireland. They form part of a group which also contains two small churches, a round tower which is still 110 feet high, and several tombs and memorials. It is intended to have a cast of the tallest of the crosses in the Dublin Museum, and perhaps another at South Kensington. The rumour was spread that the workmen employed had scraped the surface with sharp instruments which had disfigured the carving, and a question on the subject was asked in the House of Commons. The Secretary of the Treasury, in reply, explained what was done. Before the plaster could be applied it was necessary to remove the moss and lichen from the hollows of the cross. This work was entrusted by the Science and Art Department to a skilled Italian workman of artistic training, who had been for some time in their service, and had always done his work with the greatest care. He at first used a steel instrument to clear the surface, but when attention was called by Mr. PENTLAND, a local antiquarian, to the risk of injury by the process, it was at once discontinued, and the remainder of the growth removed by washing. Skilled officers had been sent down both by the Department and the Irish Board of Works, and they had examined so much of the surface as was not already enclosed in plaster. No signs of injury appeared, and it was hoped that when the plaster was removed the remainder of the surface would be found to have taken no harm.

ARCHÆOLOGY AND ODDFELLOWSHIP.

ONE of the incidents of the congress of the British Archæological Association at Peterborough was the delivery of a sermon in the cathedral by the Bishop. It was not specially directed to the members. The Sunday happened to be the annual church parade of the local Oddfellows. They assembled in a style which must make any archæological society appear as commonplace. The Oddfellows had banners and bands, regalia, sashes, medals, gold chains, and as they entered the cathedral they brought back Mr. ORCHARDSON'S *Queen of Swords* to memory, for the stout sword-bearers of the Manchester Unity held their blades above the heads of the members. Some of the members of the Corporation were adorned with sashes and badges, and unless we are mistaken there were dignitaries of the cathedral who were proud to testify that they also were enrolled in the records of members. On such an occasion an archæologist must feel as subdued as JOE TODDYHIGH when, at the banquet of his quondam fellow-messenger who was Lord Mayor of London, he saw the exalted members of the Worshipful Company of Patten Makers around him, and dare not take the most modest share of their glorification to himself. Archæology is now of little account in England, and it has to give way to Oddfellowship in various forms.

The worshipful fellows—we hope they will pardon us if we have failed to apply to them the correct adjective—may have even as well as odd members among them, and the former were not, we trust, much humbled when the Bishop ventured to compare them with archæologists. The Association and the Manchester Unity, said his lordship, at first sight had not very cognate aims or homogeneous principles. One seemed almost entirely academic, the other practical. One seemed to be concerned only with what was past, and the other entered the domain of life to-day. One had to do with things; the other was entirely personal. But each exercised an educational influence. It could not be denied, continued the Bishop, that archæology had educated to a great extent their national life and character. When everything was measured by its market price, when men more often asked, "Will it pay?" than "Is it good?" they owed a debt to archæology. In our days, when progress was throbbing in the nation's life and competition pushed aside all obstacles, archæology kept before them their debt for what they had gained from a bygone past. In that cathedral they must all feel something of that debt. Archæology made the walls and stones call into life the history and heroes of the past. The science was acting nobly in checking that material selfishness and crushing that ignoble self-complacency—the hideous progeny of wealth and ignorance—which otherwise might make havoc of the nation and its life. Archæologists had much to give, and in giving would be their blessedness. But the share of the Oddfellows as educationists was also eulogised. In their lodges social questions were discussed, and men were trained for everyday business as well as for municipal and parliamentary life. Each society had something to give, and the knowledge of that fact should help to inspire mutual respect and to remove distrust.

It was a novel contrast of past and present, but could not be said to be overstrained. Of this pushing, presumptuous, but plucky age we suppose the Oddfellows in their unities are not unsuitable representatives. We understand they encourage temperance, saving, regularity and other excellent virtues. Altogether they are said to be up to date, and for all we know to the contrary the club meetings may afford an excellent training-ground for cabinet ministers and privy councillors. Apparently the proceedings lighten the burden of existence. If happiness can be attained by wearing a sash embroidered with tinsel, although we might wish there was less barbarism about form and colour, why should not men be allowed to wear as many as they can honestly obtain? Badges and regalia can also be effectual in persuading simple folks to look on themselves as notabilities. All the paraphernalia and offices appear to be an economical aid to excite imagination and to confer self-satisfaction, and they are likely to be no less effectual than the means which other men seek and purchase at infinitely more cost and labour.

But the Oddfellows can no more ignore the past than the archæologists. The procession into the cathedral recalled those of the Mediæval guilds. But in the old days there was more taste. The guildsmen wore robes which gave an appearance of unity, of a common purpose, and which were in keeping with the regularity of the piers and other parts of the building. The Sunday garb of the members of the Manchester Unity showed an independence which is without the decorative value required in the elements of a procession when it is seen in an ecclesiastical building of the importance of Peterborough. The badges, no doubt, entitled the wearers to respectful attention, but it could not be denied they assumed more of a gilt gingerbread character when seen against the massive piers which were erected so many hundreds of years ago. If, as the Bishop of PETERBOROUGH said, the friendly societies are doing an educational work, why does not some one who has influence with them persuade the Grand Masters, Chief Marshals, and the rest of the High Mightinesses to become patrons of art as far as they can? Savages would be shocked to wear some of the ornamental appendages which are supposed to dignify respectable citizens who may one day sit in Parliament. There are plenty of young artists who would not think it beneath them to supply designs for regalia and badges. The cost of handsome originals would be insignificant if distributed over the number of copies which have to be produced every year. The certificates of membership are also generally hideous, and if all the plates could be destroyed and others of a more becoming character substituted the advantage would not be easily estimated. Regalia are only to be seen occasionally on special occasions, like visits to cathedrals, and their power to affect the taste of those who look on them is therefore only partial. But certificates of membership are generally framed and hung on the walls of members' dwellings; they are seen daily by the young, and the constant gazing at the stiffest of "supporters" and the most vulgar ornamentation cannot be beneficial to their eyes. If the members would take counsel from archæologists in such things up-to-dateness would be improved.

There is no need to hesitate about deriving aid from antiquity. Few societies who seek to be privileged are free from claims to relationship with some of the old institutions. It may rest on imaginative grounds alone, for the affinity may be as remote as the river in Macedon was from the river in Monmouth, although to enthusiastic FLUELLENS it is all one. But men cannot help believing that antiquity confers dignity. Why, the whole display of dignities among Oddfellows and kindred organisations is no more than an imitation on a small scale of the privileges which the College of Arms claims the sole right to administer in England. Grand masters and marshals are titles which the nineteenth century never invented. Why should the present repudiate the past in other things, when it cannot devise a new heraldry that will not excite our risibility like the devices of the friendly societies? Nobody need feel more of a stranger in an old cathedral than in a co-operative store or an electric telegraph office. The Oddfellows in Peterborough might if they wished believe the great building in which they heard a bishop address them was their inheritance. But it is only a part of what antiquity has bequeathed, and archæologists have as much claim to gratitude as those who are at the trouble to advertise unclaimed property of unlimited value.

The excursions and papers must have revealed to many that in the Peterborough district there is an abundance of archæological wealth which, if it were not for the enthusiasm of a few, would soon become not unlike the illusory money which the fairies once were supposed to distribute. It is of little use to have old buildings unless their history and the qualities which make them valuable are known and appreciated. That end cannot be attained if archæology is neglected. It is right to study Classic remains, and as long as education is so much based on Greek and Roman literature, the arts which are described in the books should be made as familiar as possible. But studies of that kind should not force us to be oblivious of the claims of an antiquity which has more relation to us. English life and thought are not products of the Classics alone, and we can never emancipate ourselves from the influences which were exercised upon our ancestors by northern rovers, mystics, minstrels, stone-carvers and ballad-poets during the "dark ages," and of which we need not be ashamed.

ARCISSE DE CAUMONT.

A CONGRESS of French archæologists has just been held in Bourges, and one of the addresses was devoted to the memory of ARCISSE DE CAUMONT. It was only justice to recognise his claims on the consideration of his countrymen. About seventy years ago he delivered courses of lectures on the antiquities of France; he was director of the society for the conservation of historic monuments which is now merged in the Governmental department having a similar title, he was the founder of scientific congresses in France, and was long the principal secretary of the Society of Antiquaries of Normandy. He belonged to the French Institut, the Society of Antiquaries and various foreign academies. His books are numerous, and among them the "Abécédaire" is the best known in England.

DE CAUMONT made no secret of the inspiration he drew from English archæologists. They pointed out the way which he so sturdily followed. BATTY LANGLEY'S name is a byword among us; to DE CAUMONT it marked a pioneer who prepared men's minds to receive impressions from the works which followed his own. BENTHAM'S effort to explain the importance of Ely Cathedral was no less favourably considered. The profound erudition displayed by KING in his "Munimenta Antiqua" is acknowledged, but DE CAUMONT, as became a man who drew and measured old buildings and envied the birds who lived amidst the ruins, could not accept KING'S unrestrained suppositions. It is remarkable also that, being a Frenchman, and therefore a system-monger, he should condemn the English scholar for being constantly dominated by the spirit of system, which too often acted like a will-o'-the-wisp in leading him astray in his researches. He was no less appreciative of what was done by DALLAWAY, WARTON, GROSE, MILNER, HAWKINS, BRITTON, DAWSON TURNER, RICKMAN, WHITTINGTON, WHEWELL, &c.

The French works which DE CAUMONT studied appeared to him less important than the English. Nor is the cause of the difference very difficult to discover. The English writers were not artists, they were scholars, and when they undertook to treat of Gothic architecture it was with the intention of demonstrating individual theories. They were forced, therefore, to give more attention to the details of the buildings and the relations between the various parts than if they were engaged in making pretty pictures of them. The works on architecture published in France, wrote DE CAUMONT, consist of collections of engravings or lithographs; the text is considered merely as an accessory.

It might have been otherwise if fate were more kind to French Gothic. MONTFAUCON had prepared a work on the buildings which could not fail to be influential, but the manuscript was destroyed in the fire which arose in Saint-Germain des Près. MICHEL-GERMAIN'S "Monasticum Gallicanum" vanished in the same way. LE BŒUF was unable to finish his great work before his death. The Revolution made the study of ecclesiastical buildings a crime. It required courage to rescue fragments of Mediæval sculpture from the vandals. When more peaceful times arrived many politicians continued to look askance at French archæology. LE NOIR'S attempt to form a museum of the *débris* saved from the buildings on which the revolutionists wreaked vengeance was not long supported by the Government. There was a risk for a time that French Mediæval architecture would not be more prized by Frenchmen than the mysterious buildings of South America. The efforts of the English to make the Norman buildings better known infused a new spirit, and a small band of local students such as AUGUSTE LE PROVOST, LANGLOIS, DE GERVILLE, LAMBERT, JOLIMENT, and above all, DE CAUMONT, endeavoured to become rivals to the strangers. But the studies of the Normandy antiquaries were unknown until 1824, when a society was formed which men from various parts were glad to join. By degrees interest was taken in the work, and when VICTOR HUGO and the Romanticists appeared Mediævalism became the subject of one of those spasmodic efforts which are so characteristic of Frenchmen. ARCISSE DE CAUMONT and VIOLLET LE DUC mark the beginning and end, just as VITET and PROSPER MERIMÉE are its literary representatives.

It is hard to say how the term Gothic as a designation of Mediæval architecture arose. DE CAUMONT we believe considered that BATTY LANGLEY was the culprit who first employed or reintroduced the word in that sense. Neither Goths nor Vandals possessed a distinctive style, and the Gothic nations had disappeared before the Pointed arch was seen in Europe. DE CAUMONT maintained that the style should be known as "Architecture à Ogives," or "Style Ogival," because in that way the principal characteristic would be described, while nothing was implied about the origin of the form. The divisions or developments of the style he called "Primitive" (thirteenth century), "Secondaire" (fourteenth century), and "Tertiaire" (fifteenth century and first part of sixteenth century). Our "First Pointed," "Second Pointed" and "Third Pointed" are therefore derived from DE CAUMONT.

It was more easy to make divisions than to say how the style orginated. According to DE CAUMONT, that problem caused more worry to archæologists in England than in France. He had received a letter from M. LENORMANT, who had visited Egypt, in which it was said, "L'architecture à ogives vient directement de l'Orient," and the traveller believed that if he were able to study the Persian remains of the second empire he would meet with evidence of its habitual use. How did the Pointed arch arrive in the West? It was not, said M. LENORMANT, at any fixed date by any definite agency; it was rather by "infiltration" by military, religious and commercial means, by stuffs, by furniture, by travellers' tales, by the emigration of artists.

DE CAUMONT could not accept his friend's theory in its totality. If he said the style was employed in the East before the twelfth century, it was not generally employed. It is not seen in St. Mark's, Venice, in which some artists of renown from Constantinople co-operated, nor in the cathedrals of Pisa, Pavia and Verona, which are strangers' works. Moreover, the Eastern ogives were not identical with the French ogives of the thirteenth century, and if the latter are imitations there can be no doubt about the metamorphosis which took place. Among all the varieties DE CAUMONT believed that the work of the thirteenth century was the finest. He said there was afterwards less rectitude in the lines, less harmony in the ensemble. A man must be wanting in enthusiasm and sensibility who can contemplate surviving examples without emotion; the view of one of the churches overcomes the senses like a sublime poem or a beautiful melody. But to comprehend Mediæval architecture we must realise the power of the religious belief of the time. There was, says DE CAUMONT, a tendency to turn aside from physical nature and to seek proportions from models which were not of this world. In the soaring towards the sky, in the superabundance of carving we can see, as it were, the mysticism which possessed men's minds. If the architecture of the ancients is purer as art, the Mediæval work is more touching and religious. In DE CAUMONT'S pages we have a sort of mean between the rhapsodies of symbolists and enthusiasts and the scepticism of the later Renaissance. French common sense is never better exemplified than when employed to explain the difficulties which arise in tracing the history of an art.

On the subject of design DE CAUMONT adopted likewise a middle course. We have not the names of the architects, but he does not consider the indifference to fame arose from humility. It was a co-operative age, when not only money but life, hope, thought, experience and genius became common property, when, so to speak, there were no individuals, but guilds, monastic bodies and other institutions for laymen and clerics. The associations were not the same as the francs-maçons which were formed at a later time in the Rhine valley, but they had definite principles of construction which were transmitted orally to those who were admitted, and of which no record appears to exist in conventual libraries or similar storehouses of knowledge.

The second period DE CAUMONT considers to be an intermediate stage between perfection and decline. The characteristics are not always definite, but he impresses on his readers that modifications arose gradually, and were not all introduced simultaneously. The long wars with the English were not favourable to architecture, and when peace was restored there was so much to be repaired that unity is rarely apparent. The buildings accordingly lose some of

the effect which should be theirs, especially those of the third period. Too much value was placed on an excess of ornamentation and on the intricacy of parts. There was less of an endeavour to soar, and the profusion of pinnacles and pyramidal forms could not dissimulate the insufficient elevation. But it evidently pained DE CAUMONT to utter a word about the shortcomings of Gothic in its latter days.

Works like DE CAUMONT's depend for much of their interest on illustrations. We might add that the author is often stimulated to exertion when his artist becomes his rival. DE CAUMONT at first was able to derive no satisfaction from his illustrations. They were lithographs, so weakly drawn as to deserve to be used in order to prove from what humble beginnings the art has advanced. At a later time he was able to use woodcuts which were drawn by BLOUET, a draughtsman whose work was not unknown in England, for he was employed by Mr. PARKER, but during his primordial period DE CAUMONT was so badly served we wonder he did not abandon his undertaking.

The endeavour to make Mediæval architecture known to his countrymen by means of books should be enough to preserve DE CAUMONT's work from oblivion. But we imagine his name sounded strange to the majority of the people who heard his praises at Bourges. He did not belong to the ages of faith, but there was no bishop, monk or franc-maçon who was more loyal to architecture or more eager to see it recognised at its true value.

NATIONAL PORTRAIT GALLERY.

THE trustees of the National Portrait Gallery have during the last few weeks made the following acquisitions :—

By presentation :—

General Sir John Moore (1761-1809), the hero of Coruña, and Admiral Sir Graham Moore, his brother (1764-1843) ; two fine portraits painted by Sir Thomas Lawrence, P.R.A., presented by their grandniece, Miss Carrick Moore, in fulfilment of the wish of her late father, Mr. John Carrick Moore.

Sir John Peter Grant (1807-93), Governor of Jamaica ; painted by G. F. Watts, R.A., and part of the painter's munificent gift to the nation, the ten years' rule being suspended as on the occasion of his previous gifts.

Thomas Augustine Arne, Mus. Doc. (1710-78), the well known musical composer ; a caricature portrait based on a drawing attributed to F. Bartolozzi, R.A.

John William Norie (1772-1843), author of the well-known "Epitome of Navigation ;" a small portrait in water-colours by Buck, presented by his nephew, Mr. Henry H. Norie.

By purchase :—

Margaret Tudor (1489-1539), sister of Henry VIII. and Queen of Scotland ; attributed to Jan van Mabuse, but probably painted in the school of Bernaert van Orley. This portrait was exhibited as "Catharine of Aragon" at the winter exhibition at the Royal Academy in 1886.

Edward VI.; a small full-face portrait on panel, as Prince of Wales, painted in the school of Holbein.

Frederick, Prince of Wales (1707-51) ; an equestrian portrait, painted by B. Dandridge.

William IV.; a water-colour drawing, purchased to complete the series of portraits of English monarchs from Henry III. to Victoria (with the exception of Edward V.).

John Dryden (1631-1701), poet-laureate ; a small full-length portrait, painted by J. Maubert, formerly in the possession of Jacob Tonson, Grosvenor Bedford, Wentworth Dilke and the late John Murray, of Albemarle Street. A similar portrait from the Strawberry Hill collection is in the possession of the Earl of Derby at Knowsley.

James Craggs (1686-1721), Secretary of State and friend of Addison, painted by Sir Godfrey Kneller. This portrait was formerly in the possession of Addison at Bilton Hall.

At the sale of portrait-drawings by George Dance, R.A., by Messrs Christie, Manson & Woods, on July 1, the following twenty-eight portraits were purchased for the National Portrait Gallery :—Samuel Arnold, Mus.Doc. (1740-1802), musical composer ; John Bannister (1760-1836), comedian ; Sir George Beaumont (1753-1827), amateur, connoisseur and benefactor ; William Bligh (1754-1817), commander of the *Bounty*, admiral and Governor of New South Wales ; James Boswell (1740-95), biographer of Johnson ; Charles Burney, Mus.Doc. (1726-1814), musical composer and historian ; Sir Henry C. Englefield (1752-1822), philosopher, antiquary and man of letters ; John Hoole (1727-1803), translator of Tasso and Ariosto ; Mrs. Inchbald (1753-1821), dramatist ; Charles Incledon (1763-1826), vocalist ; Joseph Jekyll (1753-1837), wit and politician ; William Jessop (1745-1814), civil engineer and canal maker ; Robert Stewart, second Marquis of Londonderry, the famous statesman, as Viscount Castlereagh, 1794 ; John Moore, M.D. (1729-1802), physician and author, father of Sir John and Sir Graham Moore ; Joseph Shepherd Munden (1758-1822), actor ; Robert Mylne (1753-1811), civil engineer ; Hester Lynch Piozzi (1740-1821), as "Mrs. Thrale," friend of Dr. Johnson, and Gabriel Piozzi (1740-1821), her second husband ; James Rennell, F.R.S. (1742-1830), geographer ; John Rennie, F.R.S. (1761-1821), civil engineer ; Samuel Rogers (1763-1855), poet, aged thirty-two ; Sir William Scott, Lord Stowell (1745-1836), judge ; William Seward (1747-99), biographer ; Granville Sharp (1734-1813), abolitionist ; William Shield (1748-1829), musical composer ; George Steevens (1736-1800), editor of "Shakespeare" ; Horace Walpole, Earl of Orford (1717-97), aged seventy-six ; Arthur Young (1741-1820), agriculturist and traveller.

The following eight portraits have been deposited on loan in the National Portrait Gallery by the trustees and director of the National Gallery :—Izaak Walton, by Jacob Huysmans ; George, Prince of Wales, and Edward, Duke of York, with their tutor, Dr. Ayscough ; Thomas, second Lord Lyttelton, by Richard Brompton ; David Garrick, attributed to J. Zoffany, R.A.; William Godwin, by J. Opie, R.A.; Mary Wollstonecraft Godwin, by J. Opie, R.A.; Sir Samuel Romilly, by Sir Thomas Lawrence, P.R.A.; Charles Dickens, by Daniel Maclise, R.A.

These numerous additions will necessitate a considerable reorganisation of the collection, so that it may be some time before they can be all placed on public exhibition.

THE SILCHESTER REMAINS.

THE whole of the relics discovered during last year have recently been removed from Burlington House to Reading Museum, and are now in a great measure arranged in the cases in the Silchester Gallery. We are enabled to state (through Dr. Stevens, the hon. curator), says the *Reading Mercury*, that the series is not large, and consists of the ordinary articles in glass, pottery, iron, bronze, Kimmeridge clay, &c.; but some of the toilet objects, such as the brooches, are of peculiar beauty from the brilliancy of their enamels. The pottery is of the usual character, but there is one very large, graceful vessel which has been named the "Jubilee Pot." A very heavy top-stone of a quern, or rather a mill for grinding corn, is unlike any hitherto discovered. From its character it must have been worked by machinery. Two large tubs have also been received, which were taken from the bottoms of wells. The Romano-Britons appear to have been peculiar in the management of their water, what with tubs, linings of oak slabs and other methods of constructing their wells. The coins are distinctly worth noting from the number found of the usurper Carausius. His usurpation extended to about seven years, yet during that period more than 300 of his issues are known. Having power as commander of the Roman fleet he used it to establish his supremacy, and there is no doubt his large coinage was intended to make his assumption of imperial power widely known. It would be a great acquisition if among the Silchester coins a specimen can be found similar to one in the collection of the late Mrs. Roach Smith, where the head is rendered facing instead of in profile, and is considered as intended for a portrait of the emperor.

Several learned societies have visited the Silchester Collection during the last few weeks, including the Bucks Archæological Society and the Archæological Society of Bristol and Gloucester. Both these societies were accompanied by Mr. W. H St. John Hope, who gave excellent demonstrations on Silchester and on the collection generally.

THE CONSULTING ARCHITECT OF THE EDUCATION DEPARTMENT.

AN application has been made by Captain Grice-Hutchinson M.P., to the Education Department in reference to the scheme for the higher-grade school at Aston being sanctioned when a town's meeting to protest against the proposal had been announced, and also with regard to Mr. E. R. Robson, a Departmental official, acting as assessor to the Aston and other School Boards and receiving fees and other emoluments. In respect to the latter matter Captain Grice-Hutchinson has been informed that the method of allowing Mr. E. R. Robson, consulting architect to the Education Department, to act as arbitrator in competitions of plans for Board schools is not regarded as altogether satisfactory by the Education Department. But this system is part of the terms of Mr. Robson's engagement as architect, and it is stated that it could not be abrogated without doing him an injustice, unless his salary should be so increased as to include the amount now received by him from fees. The decision of competitions is not part of Mr. Robson's official duties. A School Board can select any architect they please for that purpose.

LAMBETH PALACE.

AT the last meeting of the Lambeth Vestry the following letter from Earl Stanhope was read:—"I am anxious to call attention to the great injury which is occasioned to the exterior of Lambeth Palace by the action of chemical smoke fumes from the neighbouring pottery works. The stone of which the palace is built is gradually peeling off, and has already considerably decayed. I, as one of the Ecclesiastical Commissioners, and therefore well acquainted with Lambeth Palace, have watched for some years the gradual destruction of the walls, and I have had several conversations on the subject with the late Archbishop of Canterbury. The particular works complained of are Messrs. Doulton's works and Messrs. Stiff's works. I cannot but think that the smoke issuing from their chimneys might be in some way further consumed, but I venture to hope the Vestry of Lambeth will kindly consider the whole question."

Lord Stanhope enclosed a communication received by him from the County Council, which stated that the duty of suppressing such nuisances did not rest with the Council, except in default of the local sanitary authority, which, in the present instance, was the Lambeth Vestry. The serious nuisance and injury caused by the Lambeth potteries had been before the Council and its predecessors for over a quarter of a century. Nearly all the trees planted on the Albert Embankment were destroyed by the fumes, and for some years past the Council had been pressing the Vestry upon the subject.

It was decided to inform Earl Stanhope that the only grounds upon which the sanitary authority can proceed are those of public health; that the medical officer is of opinion that the experience of the district does not show that the fumes issuing from the potteries are injurious to the health of the inhabitants of Lambeth, and that, on this ground, he has seen no reason to take any action against the owners of these potteries, but that he will give further attention to the special appliances used therein to reduce the fumes to a minimum and present a special report on the subject, with the view of having any further improvements, if necessary, carried out.

FRENCH AND BRITISH ART.

ON Saturday last the Lord Mayor gave a dinner "in honour of art," to which several French and English artists were invited. His lordship, in proposing "French and British art," said there were few present who were not either artists or those who favoured art. He had invited them together that they who loved and supported art should do honour to those who produced it. They had had many art exhibitions at the Guildhall, all of which had attracted large numbers of visitors. This year they had selected artists from France to exhibit their works, and the exhibition had been as successful as any of its predecessors. He was deeply grateful to the many French artists who had honoured him by their presence. He was sure that the members of the English Royal Academy were delighted to meet their brothers in art from France. England and France were the two nearest neighbours, and he saw no reason why they should not be the two greatest friends. He hoped that that meeting would not be a stumbling-block in the way of their being greater friends. England had had its great artists—artists from whom the French had taken many a lesson—their Constable, their Sir Joshua Reynolds, and many others, and they in England had taken many a lesson from those who had produced art in France.

M. Armand Dayot, as the delegate of the French Government, replied in his own language to the following effect:—When selecting me for the great honour of representing him, the French Minister of Public Instruction and Fine Arts charged me to express his regret for his inability to accept your lordship's invitation, and his regret is the more acute because your fête is a brilliant glorification of French art. I hope I may be permitted to express my desire, which is no doubt that of all my countrymen who are present, that a special exhibition of English art will also be held in Paris. I am confident it would obtain a success not less remarkable than that in the Guildhall. Of course we shall have the opportunity in 1900 to admire the results of the efforts of the modern English school that abounds in young and daring talent, as well as strong and original personality. I can anticipate that gratification, for I have always had a peculiar affection for the native elegance and fertile independence of the English school, a confession which I the more gladly make as my illustrious compatriot Sir Edward Poynter is before me, for Paris was his birthplace, for which Frenchmen have the right to feel flattered. But the exhibition of English art in 1900 would attain more interest and be more productive of instruction, if besides the works of living artists the French public were also able to admire a comprehensive collection of the older English masters, of which only an occasional exhibition is to be seen in French galleries. Such an exhibition of English art from your modern "primitifs" to your contemporary pre-Raphaelites is both needed in the interests of æsthetics and as an expression of gratitude. In order to display English works we shall have adequate buildings, and I have no doubt our two great societies of artists will endeavour to emulate the magnificent and successful example of the Corporation of London in honouring French art. From such interchanges of impressions under the most noble of forms, such intellectual fêtes, such pacific and brilliant manifestations of the genius of humanity, the people of the world, who were destined to live amidst peace, light and beauty, could not fail to derive courage, consolation and hope. In taking the initiative in the exhibition of French art you, my Lord Mayor, have enabled us to witness the triumph of our artists, and in their reception to find evidence of cordial sympathy which cannot be forgotten.

Sir Edward Poynter, P.R.A., said:—My Lord Mayor and gentlemen, I must confess that, in responding to the toast just proposed, while I thank you for the honour which you have done me in coupling my name with it, I feel a certain embarrassment—in the first place, an *embarras de richesses*, for I presume that you would not wish me to enter on the impossible task of exhausting the subject of British art on this occasion, and it is not easy to select from a theme so wide what may be appropriate to an after-dinner speech. In the next place I find myself in a difficulty in the presence of the numerous and highly-distinguished representatives of foreign art who are your guests to-night, for if I sound before them the praises of the British School of Painting, as is my obvious duty, as an Englishman and President of the Royal Academy, I can hardly help incurring the charge of national egotism. I would rather, therefore, that the task of responding for foreign art had fallen to me, and that that of dealing with the merits of our own school had been left to the generosity of M. Bouguereau, or M. Constant, or M. Carolus Duran, or some other of your distinguished guests. I should then have been able to dwell, with a plenitude of enthusiasm which comes of an intimate knowledge of French art and of personal acquaintance with some of its members, and which I must deny myself in speaking of our own artists, on the great qualities which enrich that great school—qualities so admirably displayed to us in the representative collection of French pictures which the liberality of the Corporation of London has enabled us to enjoy at the Guildhall. I must, however, perform the duty which you, my Lord Mayor, have imposed upon me, and make some reply to your wishes for the prosperity of British art, to which the toast you have proposed gives expression. There are two elements which have gone to form the British art of to-day. It has, to begin with, an originality and a sturdy independence of its own, but it also has another very marked characteristic in its readiness to adopt, to assimilate and make its own what is good—perhaps even sometimes what is not so good in the art of foreign countries. Thus, while we have seen in the last half-century artists of purely English habit form a school and rise to the highest eminence, on the one hand, through an ardent study of nature, as seen with English eyes amidst English surroundings, as in Millais, and, on the other hand, as in Rossetti and Burne-Jones, through a sympathy, also peculiarly English, with the exquisite traditions of the past in poetry and painting, we have also seen numerous earnest students who, less self-reliant, and feeling that the English art of Hogarth, of Reynolds, of Gainsborough and of Turner had so worked itself out in the course of years as to have degenerated by the middle of this century to a somewhat trivial mannerism, went abroad to Germany, to Belgium and to France—principally to France—to acquire the instruction which they perceived was not to be had at home. As, my Lord Mayor, you have said, our artists have taken many a lesson from our French friends. Among these I may cite, first, Dyce—an artist of the highest gifts, now almost unrecognised, whose style was inspired by the rather pedantic resuscitations of Overbeck and Cornelius; and more conspicuously Leighton, our great president, a distinguished example of an Englishman, whose studies were almost cosmopolitan, bringing to his own country and applying in his own way the brilliant and accomplished style which he had acquired abroad. Both these distinguished men took the best that was to be had from foreign sources in their time, but neither of them was a servile imitator of any school, and they always remained individual and English. But the greatest impetus to this desire for learning more than could be obtained at home was unquestionably by the exhibition at Paris in 1855, the first international exhibition of art. The exhibition opened the eyes of our countrymen to that brilliant school of painting then at its zenith in Paris, while it showed us, no doubt, some of our own shortcomings by the close comparison which could there be made with the splendid accomplishments of French art. It is hardly too much to say that to English artists of that time the names of Ingres, Flandrin, Gleyre and other distinguished representatives of the Classic school in Paris were virtually unknown; and still less known, if possible, were Delacroix, Decamps, Hébert, Marilhat, Robert-Fleury and a

host of others who formed the romantic school. I well remember the effect of that exhibition upon myself, and the enchantment of seeing for the first time the collected works of Decamps, a conspicuous feature of that exhibition, of Hébert, of Delacroix and of Hamon, that most delicately fantastic of the neo-classics. A new horizon was opened out before my eyes, their works were a revelation, and I was, I believe, the first of our artists who went to Paris to study. Soon others followed, more numerous as years went on, and drawing from that great school some of the qualities, both solid and brilliant, which characterised it and infused fresh vitality into English art. The art of landscape painting, also, in common with the rest of our school, had at that time lapsed into a conventionalism which smacked of the landscape of the stage, and had lost touch with nature; and it was contact with the powerful French school of that time, led by Rousseau, Daubigny, Corot, Dupré and others, quite as much as the more elaborate fidelity and earnest study of nature of the pre-Raphaelites at home, that so invigorated our landscape artists that they are now, I think I may say, second to none. Thus the art of Constable, to which you, my Lord Mayor, have already alluded, and to whose influence the French painters readily admit their own great school of landscape was due, has returned to us after long years from across the Channel in a new and invigorated form. The position which English art now occupies is a high one. I have carefully avoided any allusion to living artists, whether English or foreign, but I again mention the exhibition of British art at Brussels last year, being, as it was, more completely representative of our school than any collection of English paintings which has hitherto been seen abroad, as having gained us a free and liberal acknowledgment of this high position from foreign artists. Our English Luxembourg also, the gallery of British art on the Embankment, although far from completely representative of the modern school—our latest deceased great artist not being seen there at all, and others only inadequately—is a collection to be proud of. M. Armand Dayot has been good enough to express hope that we shall put forth our best efforts for the forthcoming exhibition of 1900 at Paris. If we do so I am certain that we need fear no competition, for I take it that British art can now make a display very different from that which we were able to put forth in 1855. If so, it will be due not only to the force of native genius as displayed in our greatest men, but to the English desire to learn wherever there is something to be learnt, and to the English capacity for adapting and appropriating what is best in the art of other lands, as we have adapted and appropriated to the best of our ability what we have learnt from our brilliant neighbours across the Channel. My Lord Mayor, I thank you again for connecting my name with this toast, and for your warm expressions with regard to British art.

After dinner the Lord Mayor was presented with the Order of Officer of the Legion of Honour.

THE HIGHEST OFFICE BUILDING IN NEW YORK.

THE steel cage construction of office buildings had its genesis less than a score of years ago, says the *Engineering Record*, and it may reasonably be assumed to have reached the zenith of its development, at least so far as height is concerned, in the building now under construction for the Ivins Syndicate, on Park Row, New York City, directly opposite the Post Office. From the head of its pile foundation to the top of the domes this structure will have the enormous height of 424½ feet, and it is probable that such a height will be rarely if ever hereafter found desirable and profitable for an office building. The plans for this building were prepared two or three years ago, and the preliminaries for construction were begun, but for various reasons were delayed and suspended for a long time. Recently, however, the obstacles have been surmounted, and the progress has been rapid. The steel framework, the erection of which was begun in 1897, is all in place, and the building may be ready for occupancy by the middle of the summer.

The foundation excavation was carried down 34 feet 4 inches below the curb, or to about 10 inches below ground water-level. Heavy sheet piling was first driven around the edge of the pit, and precautions were taken to avoid endangering the safety of the adjacent structures. The excavation and pile-driving disturbed the security of the adjacent old buildings, as their walls and foundations were not carried to any considerable depth nor built with sufficient strength to endure much vibration. Indeed, the six-storey building on one side proved so weak that it was necessary to remove the party wall, support the outer ends of the floor-beams on girders and shores, and rebuild the foundations and brickwork. To secure a stable support for these walls during and after the excavation of the new cellar they were carried on bottom sills which rested upon the tops of 6-inch wrought-iron pipes, 4 feet apart and about 20 feet long, which were jetted down under pressure until they were sufficiently below the proposed bottom of the excavation, and were considered to have developed enough skin friction to secure their stability. They were sunk in 10-feet sections, coupled together by outside screwed sleeves. Similar underpinning was required for a building on the opposite side of Theatre Alley, where nearly the whole street had to be excavated in order to permit a long and deep distributing plate girder, which weighed nearly 55 tons, to be lowered into place. The outer walls were supported in the ordinary manner by needle beams and crib work, while their original foundations were removed and solid new brick walls and footings were carried down slightly below the level of the new excavations. All of this work presented great difficulties, occasioned much anxiety and expense and caused considerable delay on the new building. After it was accomplished the construction of the steel work proceeded more rapidly, except as it was hindered by the occurrence of labour troubles.

Before the construction was begun an exploration of the site was made by water jet test-pipes, and this indicated the presence of a uniform bed of fine wet sand, extending 94½ feet or more to hard pan or bed rock, and in this sand about 3,900 14-inch spruce piles were driven to a refusal of 1 inch under a 2,000 lbs. hammer falling 20 feet. The piles were driven about 18 by 24 inches apart on centres in the closest position, and were calculated to receive a maximum load of 16 tons each. They are capped with granite blocks 10 inches thick and brick piers loaded to 15 tons per square foot. Some of the columns carry total loads of as much as 3,000,000 lbs. each, and single sections of them weigh 58,000 lbs. each. The whole structure covers an area of 15,000 square feet, upon which is distributed a total load of 65,200 tons. Of this about 3,740 tons is estimated for possible wind pressure resulting from a computed pressure of 30 lbs. per square inch upon the exposed surface of buildings and 9,000 tons for the weight of the steel framework. Concrete made of 1 of sand, 2 of Portland cement and 5 of 2½-inch stone was rammed to a depth of 1 foot around the top of the piles. The underpinning of the adjacent buildings was carried to a depth of 34½ feet. As soon as the excavation was begun, the sidewalks were carried over it by heavy timber bridges calculated to carry 300 lbs. per square foot, with a double-roofed storage platform above floored with three 3-inch plank, calculated to sustain a load of 500 lbs. per square foot. Two feet beneath this platform, and about 10 feet above the sidewalk, was a slightly pitched surface of thin matched boards that served to form a roof and protect pedestrians from any possible drip or dust. The upper platform was utilised for the storage of considerable quantities of cut stone and masons' supplies, as well as for the location of some of the contractors' offices, and afforded an opportunity for the carvers and other workmen to perform the necessary operations that could not well be done before the material was shipped.

The grillage beams are set on granite caps in a one-half inch bed of Portland cement mortar, and where spaces of more than one-half inch exist between the beams and the caps they are supported on layers and cross layers of thin flat steel bars, with the interstices filled with grout. They receive their proportionate parts of the weight of the superstructure either directly from the extended bases of single columns in the cases of small piers, or from sets of columns, through multiple webbed plate girders, distributing the loads over the larger piers. The general design of the building and its principles of construction are similar to those of the American Tract Society building. The sixty-six lines of columns are built of angles and plates in box section, heavily web-spliced in alternate lines at every second storey. The floor girders and beams are rigidly rivetted to them, and being trussed with systems of diagonal rods virtually form horizontal diaphragms, with a continuous hollow brick floor construction to resist lateral strains. There are also sets of diagonal braces in the vertical planes of some of the interior columns, which together constitute vertical trusses to resist the pressure of wind strains, against which the building is additionally stiffened by heavy latticed girders, built into the exterior walls and around the open courts. The walls are simply thin brick and stone curtains to enclose the interior, exclude the weather and afford surface for architectural treatment. The lanterns and domes have frameworks of steel columns, beams and curved rivetted ribs, and are covered with 18-ounce copper on steel frames, and the heavy cornices are made of stamped copper carried on iron brackets cantilevered out from the main construction.

The outside wall columns are carried 2 feet above the roof beams and connected with a belt course of 3-inch channels across their tops under the coping, into which the terra-cotta balustrade is securely dowelled. All of the columns throughout the building are fireproofed with 4 inches of brickwork. The inside of all walls below grade that are exposed to contact with natural or filled earth is faced with hollow brick bonded by headers extending into the main brick wall at every sixth course

and all of the substructure is covered to a height of 2 feet above the excavation with a triple layer of hot asphalte and paper. Four layers of the same waterproofing material are also laid on top of the ¾-inch tiles composing the roof surface. The floors are all built of 10 and 12-inch hard-burned, hollow-end construction tile, laid in cement mortar and filled in above with concrete composed of eight parts cinders, two parts sand and one part cement. The whole weighs 65 lbs. per square foot for the 15-inch beam construction, and 45 lbs. for the 10-inch beams. All floors are constructed to carry a load of 200 lbs. per square foot. The skew back tiles are lipped to protect the bottom flanges of the beams, and all partitions are built of hollow tiles, which are 3 inches thick. All the mortar used throughout the building is composed of washed sand, three parts, and Atlas Portland cement one part, mixed dry by machinery, and delivered in bags to the building where it was distributed as required and wet up to the proper consistency in tubs adjacent to the places where it was used. It is considered that satisfactory results were secured and the practice was found to be of advantage during the labour troubles which handicapped the construction.

The principal dimensions of the building are as follows:—Park Row front 104 feet, Anne Street front 20 feet, Theatre Alley front 48 feet; height, twenty-six storeys from curb to main roof, four storeys in each tower and one small storey in each dome, and lantern above domes, besides cellar, basement and sub-cellar below the curb, making a total of thirty-three storeys from foundation to the extreme portion of the accessible interior. The height from the head of the piles to the base of the flagstaff, which is the highest accessible portion of the building, is 424½ feet. From the street level to the same point is 390¾ feet. From the street level to the top of main cornice is 336 feet. The heights of the different storeys from floor to ceiling clear are as follows:—Cellar, 14 feet; basement, 10 feet; first storey, 16 feet 11 inches; second storey, 12 feet 11 inches; third storey, 11 feet 11 inches; fourth storey, 10 feet 11 inches; fifth to twenty-fifth storeys, 9 feet 11 inches; twenty-sixth storey, 12 feet; twenty-seventh, twenty-eighth and twenty-ninth storeys, 8 feet each. The main front on Park Row is of the Renaissance type, with a wide reveal in the centre which extends to a heavy overhanging main cornice at the roof, and is crossed by sub-cornices or belt courses at intermediate storeys. The two sides of the building form projecting pavilions, which terminate in circular towers above the roof line with smaller octagonal corner turrets surrounding them. Doric columns, three storeys high, ornament the front at the street level, and are capped by a Doric cornice. At the fourth storey there are four sculptured figures of heroic size. The front walls to the top of the third storey are of granite, thence to the top of the sixth storey of Indiana buff limestone, and thence to the top of the cornice they are of brick, with terra-cotta and stone trimmings. The roof is covered with concrete to a depth of 4 inches above the flanges of its girders.

The building will be heated to 70 degrees in zero weather by direct low-pressure or exhaust steam radiators, operated by a 16-inch main in the basement. To prevent undue heat radiation the boiler-room has a double ceiling, composed of T bars suspended from the main ceiling and covered with wire netting, on which sectional magnesia blocks 1½ inches thick are laid, and plastered with two coats of magnesia plaster, so as to enclose a 3-inch insulating air space. The plumbing system is of the ordinary modern equipment for high office buildings, with screwed galvanised steel pipe sewers that empty directly into the street sewers. For the sub-cellar the drainage is collected into a steel tank cesspool, and periodically pumped into the main sewer. The water-supply is derived through two 4-inch connections, with independent street mains, and after being filtered is pumped into 20,000-gallon storage tanks at the top of the building, whence it is distributed through a single system of down supplies controlled by a series of valves in the cellar. The extreme pressure for fixtures at the lower levels is reduced by special throttling of the outlets in the different fixtures. The building is equipped with ten main passenger electric elevators, one of which runs from the cellar floor and mine from the basement floor to the twenty-sixth floor, besides which there are two elevators, one in each tower, which will run from the twenty-sixth to the twenty-ninth floor. Each of these elevators is designed for a working speed of 500 feet per minute, or a possible speed of 700 feet per minute, and the test requirements were that each car containing 300 lbs. of live load should make 200 full round trips in ten hours. Mr. R. H. Robertson, New York, is the architect of the building, and Mr. A. Pauli, of his staff, has the general charge of the plans and details. Mr. W. H. Gorham is the architect-superintendent of the site. Mr. G. W. McNulty, M.Am.Soc.C.E., was retained as consulting engineer on foundation piling-work, and Mr. Nathaniel Roberts as consulting engineer of the iron construction.

ROYAL ARCHÆOLOGICAL INSTITUTE.

THE members of the Archæological Institute assembled on the 19th inst. at Lancaster for their annual meetings. The president is Sir Henry Howorth, M.P. for South Salford. The first meeting was held at noon, when the Mayor of Lancaster, attended by several members of the Corporation, received the members of the Society at the Town Hall and bade them hearty welcome to the county town. Sir Henry Howorth delivered his presidential address, in which he traced the history of Lancashire from the earliest times. He showed how the county had played an important part in the nation's history, and referred in detail to the part it had taken in the Wars of the Roses, the Great Rebellion and the Reformation. In the afternoon Mr. W. O. Roper, F.S.A., read a history of St. Mary's Church, and Mr. Austin gave a *résumé* of its architectural features, especial interest being centred in the doorway (discovered on Monday) in the west wall, which is a good example of the Decorative period. In the evening Dr. Robert Munro, secretary of the Society of Antiquarians in Scotland, lectured on "The Relations between Archæology, Chronology and Land Oscillation in Post-glacial Times."

The members on Wednesday visited the famous Furness Abbey, which was described by Mr. W. H. St. John Hope, assistant secretary of the Society of Antiquaries. Mr. Hope is an authority upon the monastic establishments of the Middle Ages, and his description included the result of the excavations carried on at the abbey during the past three years, including the discovery of what is believed to be the abbot's kitchen. It seems to have been of the thirteenth century, and to have had fireplaces with projecting stone hoods. It also had a groined roof springing from a central column. Later in the day the party visited the Peel of Fouldrey, which was also explained by Mr. St. John Hope. In the evening the historical section of the Institute was opened at Lancaster by an address by Mr. J. Holme Nicholson, a president of the Lancashire and Cheshire Antiquarian Society. A paper on the history of the Lancaster School was read by Mr. A. F. Leach, who visited Lancaster in connection with the Charity Commissioners' proceedings concerning the preparation of the scheme for the government of the school which has recently come into operation.

The members had another enjoyable excursion from Lancaster to Borwick Hall, near Carnforth, famous in Jacobean history, and Levens Hall, the seat of Captain Bagot, M.P.

Mr. Roper's remarks at the meeting of the historical section on the preceding evening created a good deal of interest. He controverted what had generally been accepted as facts in Lancaster history. He denied that Overton Church was the oldest in the district, contending that Heysham was far older and more interesting. He also said there was much doubt about the history of Lancaster Castle. There was not a scrap of Roman masonry about it. The keep was Norman, and the circular tower was not the oldest part, whilst the Well Tower and Adrian's Tower were still more modern. He suggested that John o' Gaunt had nothing to do with the building of the gateway tower as was popularly supposed, because the shields on the gateway showed they could not be older than 1407. John o' Gaunt had been dead some years then, and the gateway tower was probably erected by Henry V. when Prince of Wales.

From Borwick Hall the party drove to Levens Hall, where the Elizabethan mansion and Jacobean gardens were described by Mr. Curwen, of Kendal. On the way home Mr. Roper provided afternoon tea at his residence at Yealand.

The architectural section was opened in the evening with an address by Mr. J. T. Micklethwaite, vice-president of the Society of Antiquaries, and Mr. W. S. Calverley read a paper on "Pre-Norman Fragments."

WELSH ANTIQUITIES.

THE prehistoric stone walled camps of Pembrokeshire attracted considerable attention last year when the Rev. Baring Gould paid a visit to that county to inspect them, and to gather information in a locality which he is making the scene of a novel which he is now engaged upon, and which will deal with the period when the Norman occupation and power were fully established in this country. Mr. H. W. Williams, of Solva, Pembrokeshire, has recently been to see Mr. Baring Gould about the stone camps, and it is now announced that with a view of ascertaining what people were the builders of these ancient fortresses the Rev. S. Baring Gould, Mr. Robert Burnard, F.S.A., and Mr. Enys (of the Royal Cornish Institute), all members of the Dartmoor Exploration Society, will visit St. David's Head towards the end of the present month for the purpose of systematically exploring the stone fortifications and prehistoric habitations there. The ruins of the chapel of St. Non, the reputed mother of St. David, will be visited at the same time by these antiquarians.

NOTES AND COMMENTS.

THREE years ago Sir DAVID SALOMONS founded an engineering scholarship of the value of 40*l.* a year in connection with Gonville and Caius College, Cambridge. In order to celebrate the 550th anniversary of the foundation of the college the donor has increased the amount to 70*l.* a year. The Salomons Engineering Scholarship will henceforth be open to persons not yet in residence, and is tenable for three years. The person elected is to make a declaration that he *bonâ fide* intends to enter the engineering profession as a civil and electrical engineer, and will, if required by the governing body of the college, become a candidate for the Mechanical Sciences Tripos. The next examination will be held on Tuesday, November 1, 1898. Candidates must not be more than nineteen years of age on October 1, 1898. The successful candidate will be required to commence residence in October 1899. The subjects of examination will be Euclid, algebra, plane trigonometry, geometrical and analytical conic sections, elementary statics and dynamics and differential calculus, physics, including dynamics and hydrostatics, with practical work. Candidates must send their names, with testimonials of good conduct and certificate of birth, on or before Tuesday, October 25, 1898, to one of the tutors, the Rev. E. S. ROBERTS or Dr. J. S. REID.

IN New York the registration of plumbers is more of a necessity than it is likely to be in England. Unless plumbers of all classes, including masters, have their names and addresses recorded at the Board of Health, and can produce formal certificates to that effect, they are unable to recover in a law court any money which may be due to them. There is no doubt the arrangement is severe towards plumbers, and it is one which dishonest people can turn to account to evade payment of their debts; but sanitary requirements probably needed so Draconian an edict. Non-registered plumbers can be fleeced, but suppose a wooden casing is put over their pipes, or they employ other materials besides lead piping, does the edict apply? That is a question which for some time has puzzled the New York courts, and after going the round of them it cannot be considered as settled. The case arose in the following way. In December, 1894, a firm of plumbers contracted to execute work in a building in New York, and some carpentering and painting were included in the contract. After a sum of 5,229 dols. was paid, a mechanics' lien was lodged against the building for the balance of 2,625 dols. When the case was heard it was dismissed because the plaintiffs were unable to produce a certificate of registration. On appeal a majority of the judges confirmed that decision as regards plumbing, but ordered that it should be changed into one for the plaintiffs because there was plastering, masonry and painting, payment for which could not be affected by the registration edict. One of the judges not only approved of the reversal, but held that the law did not mean a forfeiture of materials and labour to an individual as a penalty for a neglect of registration. Work should be paid for. It was the duty of the authorities to have the penalties inflicted for violation of the law. As the reversal was only lately obtained the case may have to assume other phases before it comes to an end.

ANY one who has an interest in figures in connection with organic life will find gratification in the "Report on the Bacteriological Examination of London Crude Sewage" to the London County Council. At Barking 7,260,000 micro-organisms are found in a cubic centimetre of sewage; at Crossness the number was 5,290,000. One advantage of giving attention to such infinitesimal growths is that sewage contamination of natural waters can be detected with a delicacy to which no chemical process is equal. It may be some consolation to Londoners to learn that "a large number of bacteria, other than those already discussed, have been met with in the cultivations of the different samples of sewage. Many of these belong to species hitherto not described, or described in so incomplete a manner as to make comparison and identification difficult if not impossible. It is hoped that in further reports space may be found for the description of a few of these bacteria. As showing the great number of bacteria of different sorts in sewage it may be stated that in a cultivation of Crossness crude sewage, containing so minute a quantity as 0·00001 cubic centimetre of sewage, there were present at least five distinct species of micro-organisms out of a total of thirty-four colonies." There is a large plate to illustrate the report.

A SYNDICATE was lately formed in Birmingham for the purpose of purchasing some works of the late Sir E. BURNE-JONES which could be added to the collection in the Municipal Art Gallery. Five examples have been acquired. The largest is the design for a window at East Hampstead, having for subject "The Last Judgment." Another drawing has "Elijah in the Wilderness" for subject. A figure of "Mars" was probably intended for a series of the signs of the Zodiac. A design in pastel shows the "Three Graces." The fifth is an upright sketch called "Helen at the Burning of Troy," which from being unfinished suggests more power than is seen in all the perfected work of the artist. These additions to the gallery are supplemented by some pictures lent by Mr. J. T. MIDDLEMORE, viz. "The Garden of the Hesperides," "Miriam," "The Challenge in the Wilderness," "Christ Blessing Little Children," "The Dream of Lancelot," and studies for the Gorgon's head and for the MAGDALENE in the "Morning of the Resurrection." The peculiarity of the works suggests the advantage of having at least one room devoted to a man who, like DAVID COX, was a credit to Birmingham. The South Kensington Museum has been enriched by three of Sir E. BURNE-JONES'S designs. One is for the mosaic of the "Tree of Life" in the American church of St. Paul, Rome. The second design is part of a window at Castle Howard, and shows the Evangelistic symbols. Mr. C. FAIRFAX MURRAY has presented a model of the apse of the Roman church, with a sketch of the mosaic decoration, the subject being the "Heavenly Jerusalem." Unfortunately the model has been damaged, and two of the figures were obliterated.

THE competition for the Legislative Palace in the city of Mexico has been concluded. It was considered that not one of the designs was worthy of the first premium. Mr. ADAMO BOARI, formerly of Ferrara, but now of Chicago, has received the prize of 1,100*l.* One of 1,000*l.* was awarded to Messrs. BURNHAM & WEBER, Chicago. Messrs. PIO PIACONTI and FELIPO NATALETTI, of Rome, have gained the prize of 900*l.* The third prize of 700*l.* was won by Signor PIETRO PAOLO QUAGLIA, of Naples. Messrs. RAMSOO & Co., of Mexico, have obtained the gold medal with 100*l.*, and Signor GIACOMO MISARUGA, of Rome, the silver medal and 100*l.*

ALTHOUGH many Roman objects are found in Bath, it cannot be said that explorers are equally fortunate in discovering remains which are proofs that Christianity was a power in the district at an early time. Much interest is therefore attached to a relic which was lately discovered during some recent excavations at the Kingston Baths. It is a cross worked on a circular plaque about 3 inches in diameter, and bears the names of the four Evangelists together with a Latin inscription. It is in a perfect state of preservation, with the exception of the date, and is believed to be a consecration cross of the seventh century. It is the first specimen of Christian antiquity discovered in connection with the baths of Bath. At a late meeting of the baths committee the cross was produced by Major DAVIS, the city surveyor of works, who has been most fortunate in bringing to light important evidence of the state of Bath during the Roman occupation. He was requested to confer with the authorities of the British Museum with a view of obtaining an authentic report upon it. Major DAVIS stated that it was exceedingly valuable and that nothing like it had ever been found in England before.

VILLA AT CANNES, FRANCE.

EXHIBITION OF THE NATIONAL SCULPTURE SOCIETY, NEW YORK.—THE ENTRANCE GALLERY. IN THE ITALIAN GARDEN.

SCULPTURE IN AMERICA.

ART is so well encouraged in the United States, it is no more than reasonable for the sculptors to endeavour to obtain a fair share of the money expended. On both sides of the Atlantic paintings attract most attention, owing in many cases to the unsatisfactory conditions of seeing works in stone, bronze and clay. What can be done by sculptors is, therefore, not generally known. In order to remove some of the impediments to a more general appreciation of the art, the National Sculpture Society was founded three or four years ago in New York. Already the results are satisfactory. In a pamphlet published by Mr. Charles de Kay, the first vice-president, it is said :—

Plastic art has suddenly taken a part in the development of the art of the whole country which no one would have expected. To the Society, it may be said, the country owes the decorations of the Library of Congress. Through its labours the architects of the coming Public Library and Appellate Court of New York have been able to embody sculpture and sites for sculpture in their plans. Had the Society not existed, the chances are great that one of two things would have happened: these buildings would not have been adorned with sculpture at all or they would have been decorated by inferior European artists.

Be that as it may, the important thing to chronicle in connection with these exhibitions of sculpture is the widening of the working field for the sculptor, resulting from a broader view. Sculpture is seen under the most diverse aspects, using the most varied materials. Wood, bronze, silver, ivory and iron, terra-cotta and porcelain, purest Carrara and the splendid coloured marbles of America and Europe, all can be levied upon by the sculptor without fear that pedantic critics and dilettants shall raise the rumpus that deafened poor Gibson's ears. We have plenty of realistic portraiture in sculpture—bas-relief and bust, and standing and equestrian figure ; the time is ripe for ideal pieces as full of sentiment and poetry as a beautiful landscape or marine. We have no Medici to open a garden for the encouragement of our young sculptors. But the Sculpture Society looks forward with hope to the time when its finances will permit of the publication of small limited editions of ideal statuary fitted for the adornment of the drawing-room and the library, the merchant's office and the music room, the school and the boudoir. Such things are better calculated to quicken the love for sculpture than equestrian monuments and the more ambitious statuary of public squares and formal gardens.

A beginning has already been made by the casting of statuettes and small groups, the work of American sculptors, for sale at prices suited to ordinary purses. The reduction machine recently introduced permits of an exact duplication of large groups and statues on any scale, so that a sculptor can now enjoy the royalty on reductions of any work which carries enough weight with the public to warrant the expense. This should be another means of making the people familiar with good sculpture.

The National Sculpture Society is organised for men and women interested in sculpture as well as for professional sculptors. It is not only national, as the membership list shows, and as one sees by the presence of work from sculptors of Washington, Chicago, Boston, Baltimore, Philadelphia and of smaller cities of the Union, but up to a certain point it is international—witness the number of foreign-born sculptors in its ranks or merely exhibitors ; witness the sendings of European artists. Upon its short but useful life, upon its slowly growing membership, upon the tokens of confidence in its judgment received from the public, the Society looks with reasonable pride, trusting to continue to warrant that confidence all the more if placed in such a position as to widen its sphere of usefulness.

The Society is often asked to give, through committee, its advice on some public monument in New York or other city. And though its confidence and right to respectful treatment have been abused occasionally by men who first sought counsel and then overrode the advice received, the Society remains ready to do what it can to encourage a more economical and rational way of adorning cities and buildings with statuary. It stands ready to help monument committees in all parts of the Union, but very naturally it expects ordinary courtesy and consideration for its disinterested efforts.

We are glad to aid the National Sculpture Society by giving a couple of views of the exhibition of this year, which was held in the galleries of the American Fine Arts Society, New York. In the plate of the Italian Garden the central group is a part of Mr. D. C. French's monument to John Boyle O'Reilly, in Boston. It represents *Erin between Poetry and Patriotism.* O'Reilly was connected with some of the insurrectionary movements in Ireland, and was compelled, like many other able men, to become an exile. He found his way to Boston, and as a poet and editor was one of the intellectual forces of that city. On the right is a plaster model of the bronze statue of *Solon* for the Library of Congress, by Mr. Wellington Ruckstuhl, of New York. On the left is another figure from the same building, *Herodotus*, by Mr. D. C. French, of New York. Nearer the front is a group, *Boy with Geese*, forming part of a fountain, by Mr. K. T. F. Bitter, of Weehawken, N.J.

In the plate of the Entrance Gallery on the left is seen the bronze statue of *Hahnemann*, by Mr. C. H. Niehaus, of New York. The reliefs with delicate ornament which are utilised to flank a doorway are part of the memorial of the homœopathist. Near this work is another relief, a part of the Garfield Monument, Washington, showing the President as student. It is by J. Q. A. Ward, of New York, president of the Society. The bronze group in front of Hahnemann is called a *Symbol of Life*, by Mr. Charles Grafly, of Philadelphia. The seated statue on the left is a portrait of Dr. Pepper, by Mr. Bitter, and the large standing figure is Rufus Choate, a prominent politician, by Mr. French. The bronze doorway is from the Library of Congress, by the late O. L. Warner. The group of children is called *The Little Architect*, by Mr. Johannes Gelert, of Chicago. There are also portrait-busts, some of which were coloured ; small groups of various sorts, medallions, &c. The views alone are sufficient to prove that "the National Sculpture Society is doing public work of the highest educational sort, by showing how towns can fit with statuary their public squares and buildings, rich men adorn the gardens about their country seats, citizens decorate their winter gardens and conservatories ; it means at the same time to give to sculptors the chance to produce ideal statuary for the house, seals for corporations, stamp and coin designs for the Government, medals for days of commemoration."

ARCHÆOLOGY OF THE PETERBOROUGH DISTRICT.

THE first day of the congress of the British Archæological Association was occupied with Peterborough. On Friday, the 15th inst., the country excursions began.

Barnack Church.

The ancient church of Barnack was first visited. The Rev. Canon Syers, who received the members, also read a paper on the building. He explained that its exceptional interest from an archæological point of view lies in the wonderful example it gives of five distinct periods of Gothic architecture, the Saxon, Norman, Early English, Decorative and Perpendicular. In the transition from one stage to the other there is no sharp line of demarcation—it is a process of evolution and transition. The square tower is Saxon, but the octagonal spire is an Early English addition. The late Canon Argles, when pulling down the ancient masonry with which the Early English spire designer blocked up the west arch, discovered that the foundations were laid on *débris* believed to have been caused by the burning of the old Saxon church by Sweyn—a fact recorded by Ingulphus in 1013. There is some doubt as to the builder of Barnack Church. The most generally accepted version is that Wilfrith, an Archbishop or Bishop of York, was responsible for its erection, and this would bring the date out at about 670. Wilfrith's patron was Alfrith, Prince of Northumbria, who was connected with the district. The emblematical carvings on the tower—which are identical with known churches built by Wilfrith—strongly support the theory. SS. Peter, John the Evangelist and John the Baptist are the saints to whom he usually dedicated, and these are typified in the sculptures of the cock, the eagle and the dove. The outside walls of the church are Norman work, as is the arcade on the north side of the nave. There is also a Norman side chapel opening from the choir through a fine Norman arch. There are traces of a causeway connecting the church with the Manor House close by, which from 1189 to the time of Henry VIII. was in the possession of the abbots of Peterborough. The south arcade is in the Early English style, while the chancel belongs to the Decorative period. The east window is an almost unique example of crooked canopy work, a similar window existing in the chapel at Merton College, Oxford; and, lastly, the Perpendicular style is represented by a chapel dedicated to Our Lady, separated from the choir by an arch which claims special attention. Up to the caps of the pillars the arch is constructed of Barnack stone, while above the caps the stone is foreign. Canon Syers thinks the explanation is that the quarries of Barnack had given out, which would give the date of the chapel as *temp.* Henry VII.

The Manor House was next seen, where the relics of a Norman hall were inspected, and then the old rectory grounds, where lunch was served.

Wittering and Wansford.

At Wittering Church Mr. Charles Lynam, F.S.A., served as cicerone. It is a less pretentious building than Barnack, but apparently as old. The arch of the nave is typically Saxon, strong and rude. Wansford Church was afterwards seen, Mr. Lynam again conducting the congress over the church there. There are several remarkable features about the

church. It is Saxon, and has a tower. The chancel has disappeared, and the interior consists merely of a nave and a north arcade. Above the west end of the nave, abutting on the tower, has been constructed a quaint gallery, which is used for the choir.

Castor Church.

The fine Norman church of Castor was described by Mr. J. C. Traylen, of Stamford. The church is cruciform in plan, and dates primarily from early in the twelfth century. The finest feature of the Norman work is the tower, which is of the richest possible style of the period. Although the architecture is principally Norman, from time to time additions in the Early English and Decorative styles have been made. The fresco paintings on the north wall representing the three stages of the Christian Church were described with the aid of a paper by Mr. W. H. Saunders. The pillars of the southern arcade in the south transept were said to exhibit the finest possibilities of the Early English period. There is a curious inscription reputed to be Roman over the south chancel door.

Milton Hall.

At this house the members were received by Mr. George C. W. Fitzwilliam. The fine pictures and curiosities of the house were examined with interest. One of the most curious relics was a "christening screen," given by William the Conqueror to an ancestor of the present Earl Fitzwilliam.

Orton Longueville Church.

At the evening meeting in Peterborough a paper on the history of Orton Longueville Church was read by the Rev. Peter Royston, M.A. Orton is contracted from Overton, *i.e.* the village on the other side of the river Nene from Peterborough. The church of St. Botolph (this part of the parish is now known as "Bottle Bridge") having become a ruin, the parish was merged in Orton Longueville in 1721 by the deed of Bishop Gibson of Lincoln (Sweeting), and the stone removed from there went to enlarge the south aisle of a church for the accommodation of its parishioners. The site is marked by an upright gravestone. The parish church is dedicated to the Holy Trinity. It is an interesting structure of uniform date, being of Early Decorated character of about 1320 to 1330, and is unique. The first object which attracts attention is the fine east window, with its five lights, and an excellent specimen of the earliest form of what has been called "net tracery." The lights are cinquefoiled in the head, and a broad fillet extends round the innermost arch, with moulded interior arch and joints, with a base but no capital. The south-east window is of a very unusual type, of highly satisfactory design of the Decorated period, with three lights, cinquefoiled and having a double-feathered trefoil in the tracery. On the north wall is a single window of two lights with a quatrefoil in the head, a very beautiful design of fourteenth-century work. On the west side of the priest's door is a low sized window of three lights, now blocked, two of which were originally glazed and the third had a movable shutter. Adjacent is a stone seat from which the priest administered his alms, whilst near to this window are three "flower balls," of exquisite design, all different in appearance. On the opposite north side is a like seat to the one on the south, and it has often been conjectured why it should be there? Might it not have been for the priest who rang the sanctus bell? On the same side, just outside the altar rails, there is a sharply pointed recess, 7 inches wide and 2 feet 10 inches from the base to the apex of the arch. It has often been conjectured, what was its use? May it not have been for the depositing of the "pyx," the ornamental box with casket, in which the consecrated "Host" was preserved for the use of the sick? To the north and south of the reading-desk and pulpit have been two openings, the former of which is now blocked up. It is presumed that the ladders to the rood-screen were originally here. The south of the nave aisle has been enlarged. This was done for the accommodation of the parishioners living at St. Botolph's when the church there was abandoned. In the east are two windows of three lights of the same date as the church. Attached to the pillar in the south arcade, opposite the south door, is a brass money-box, which is generally used for offerings of women who have been churched. In the tower on the north side is a recess about 9 feet high and 4 feet in diameter, which has puzzled the brains of many archæologists as to what use it was put. It is arched at the apex, and was evidently not intended as a staircase to the belfry, as that is on the opposite side. The rector's opinion is that it was used as a confessional. On the north of the nave is a shallow cupboard in the wall. Upon opening the door there is displayed to view a painting of St. Christopher bearing Christ. It is in a very perfect condition, and is one of the largest known in this country. Beyond this is a marble tablet to the memory of Lord Douglas William Cope Gordon (by H. H. Armstead, R.A.), fourth son of the tenth Marquis of Huntly, who was M.P. for West Aberdeenshire from 1876 to 1880, and for the oun ty of Huntingdon from 1880 to 1885. In the chantry is an ab> rate monument to Lady Elizabeth Conyngham, daughter of the first Marquis of Conyngham and wife of the late Marquis of Huntly. There is also a window placed to his memory by the tenantry, and a monument erected by his wife and family. There is also a sitting figure, a beautiful tribute to Lady Mary Seymour, the wife of Lord Aboyne (by Chantrey). But we must not omit to mention the effigy of a cross-legged knight, somewhat mutilated, but very interesting as being of a date coeval with the erection of the church and probably representing the founder of it. Tradition says this was Sir Overton Longueville. The head and neck have the usual chain haulberk of the period (about 1330), a kite-shaped shield suspended by a strap from the shoulder, the baudrick or sword-belt holds also a dagger in a sheath, the figure has a long surcoat, the legs seem to be partly cased in plate armour, and the foot (only one remains) has the prick-spur. There is not a doubt that this effigy is of the date of Edward II. We must not omit to mention that above a magnificent slab of Alwalton marble is an extraordinary monument with sixteen quarterings, erected to Elizabeth Rayner, only daughter and heiress of William Rayner, of the county of Huntingdon, and wife of Henry Talbot, who died in 1629. He was a close connection of George, sixth Earl of Shrewsbury, who had the custody of Mary Queen of Scots committed to his charge in the eleventh of Elizabeth, when confined at Fotheringhay, and it is said that he passed through the old gateway at the south of the hall, and signed her death warrant the night before her execution. He had been appointed January 16, 1571-72, at the arraignment of the Duke of Norfolk, Lord High Steward of England, and after the execution of that nobleman Earl-Marshal. And now for a few words on the exterior. The tower has the appearance of being oblong rather than square, but this is due to the buttresses, which widen it somewhat on the north and south sides. The two niches on the south side of the chancel may have been used for the figures of saints, or, as someone has suggested, been originally a part of the sedilia, removed and placed there after some restoration of the church. The priest's door in the chancel has an excellent specimen of floriated iron-worked hinges. No doubt this is De Leghton's work of about 1294, and most probably belonged to an older door, and put on here when the church was built. They have the distinctive features of the stamped ornaments and the curious lappets in the inside and outside of the church at the terminations of the label mouldings and masks in notch heads which are well worthy of notice, for they are so designed as when viewed from a distance to resemble a grotesque head, no two being exactly alike in their outline. This feature is prevalent from the latter end of the thirteenth century. And to crown all, we must not omit to mention the fine wheel.

Stamford and Burghley.

On Saturday morning several members left for Stamford. Mr. J. C. Traylen, surveyor to the diocese, acted as cicerone for the day. On the bridge which spans the Welland Mr. Traylen gave a summary of the history of the town, which was considered by Sir Walter Scott to be the finest between Edinburgh and London. In the fourteenth century it was girt by a massive wall and beautified by no fewer than sixteen churches. Over the old bridge which was then thrown across the stream marched the 2,000 knights who wrung Magna Charta from King John. But the old place suffered greatly during the Wars of the Roses, and the men of the North pulled down the Mediæval beauties of the ancient city, so that most of the relics are unmistakably of the Decorated and Perpendicular styles. However, in spite of its vicissitudes, Stamford can probably trace its antiquity with more certainty than any town except London. Some of the finest churches were visited during the morning, and also Browne's Hospital. At the parish church permission was refused to enter either the chancel or the chapel of Our Lady. At Burghley House in the banqueting hall Mr. Gotch, F.S.A., gave a concise history of the building. The State apartments were afterwards visited, and the queenly relics examined.

Peterborough Gentlemen's Society.

At the evening meeting on Saturday, Mr. C. Dack read a paper on the "Peterborough Gentlemen's Society," reviewing its origin and foundation in 1730. It is now called the "Peterborough Book Society." Interesting extracts were read from the minute books of the Society. The local hon. sec. stated that the Spalding and Peterborough Gentlemen's Societies were, especially in their earlier history, much united, and are amongst the oldest societies of their kind in England. The local Society was founded on August 26, 1730, a few years after its parent society of Spalding, which was born in 1719. Mr. J. Rowell was the first president of the Society, which was formed "for the improvement of literature, and the promotion of good-fellowship and good neighbourhood." For fifteen years the Society flourished, and there was a constant interchange of valuable literature, &c., between the two kindred institutions, several gentlemen being members of both societies. A member—the Rev. Marshall—was entered as being "very con-

tentious," and in view of certain alleged misbehaviour on his part he was expelled from the Society. Further contention resulted, and the upshot was legal proceedings ; but the record unfortunately ends here, the result being omitted. From 1750 the minuting secretary seems to have been very dilatory, and from 1760 to 1770 the Society appears to have been languishing more and more. In 1803 a committee of five was appointed, and new rules and regulations were made, and from the record it appeared that two ladies had previously been admitted. It was determined, however, that no such ladies should be admitted in the future. The Society now merged into the title of the "Peterborough Book Society," which might be described as a "limited circulating library." A discussion followed in which it was pointed out that the original minute book was in the hands of the Dean and Chapter of Peterborough, though it was rather a mystery to many how it ever came into their possession. Although the Society changed from the "Gentlemen's" Society to the "Book" Society in 1830 it was still conducted something after the old lines, but it was feared that unless some greater enthusiasm were shown it would soon become defunct. It was demonstrated that in its present condition, when access to the books seemed "quite a favour," it would be better than if the treasures were handed over and locked up in the cathedral library.

Mr. J. T. Irvine said that he did not believe that anyone who approached the proper person in the proper manner would be denied the privilege of access to the literary treasures stored by the Society, for it must remain a public library. If the church were disestablished to-morrow and the treasures of the Society had been handed over to the Dean and Chapter, he supposed the Mayor and Corporation of Peterborough would claim the library just as they would claim the parish burial ground which surrounds it.

Spalding.

On Monday the 18th inst. Spalding was visited. The party were received by Dr. Marten Perry, president of the Spalding Gentlemen's Society. The first building to be visited was the church of SS. Mary and Nicholas, which, from its known history and the completeness of its plan, is of considerable interest. The present church (leaving later restorations out of the question) was built in 1284, and it had its origin in a dispute between the Prior and the parishioners of Spalding. The parishioners, it seems, annoyed the monks at their devotions by ringing the bell of the parish church at "unseasonable hours," so a contract was entered into between both parties. The parishioners on their part agreed to pay 100*l.*, and the Prior and monks on their part agreed to build a church on the site of the old cemetery. And so, in 1284, the present church of SS. Mary and Nicholas came into existence. Previous to this date there evidently was a chapel on the site dedicated to St. Nicholas. This is known, and it is corroborated—if corroboration be needed—by the fact that one of the walls of the chancel is out of the square, having evidently been built on the foundations of the more ancient Norman chapel. The church was undoubtedly cruciform originally, with a chancel, transept and nave. The transept had an east and west aisle, while the nave had a north and south aisle. There still remains a perfect specimen of the rood-loft, which is approached by a flight of circular stairs leading from the nave. The rood-screen dates from 1315, but it has been restored by Sir Gilbert Scott. He has, however, preserved the ancient form admirably, having based his restoration designs upon drawings of the original screen, and the result is a harmonious and interesting whole. The church owes a good deal to one Sir Nicholas Aldwyn, whose insignia—that of a wool-stapler—is in evidence, for he was a benefactor to no small extent. The chapel of St. Thomas à Beckett, which stands on the south of the chancel, was erected in 1315. The windows in this chapel have the distinction of being only equalled in Ely Cathedral. Otherwise they are unique. In 1360 the south transept and aisles were erected, the north porch—still standing, a monument in its entirety to his memory—being added in 1495 by another scion of the Aldwyn family. Much of the shell of the original fabric has been removed in the process of restoration. Galleries once existed all round the church, but these have been mercifully removed. The quarterly meeting of the Spalding Gentlemen's Society, an archæological, antiquarian and literary society, was attended. Dr. Perry, president, gave the history of the Association, which owes its inception to Maurice Johnstone. The library contains a collection of old books, registers and manuscripts. The visitors also examined the library attached to the church of SS. Mary and Nicholas, consisting of 600 ancient volumes, antique and of consuming interest.

St. John's Church, Peterborough.

On the return to Peterborough the members visited St. John's Church. The vicar, Rev. L. T. Jones, M.A., conducted them over the church and called attention to the ancient embroidery—late fifteenth-century work. Admiration was expressed for the lofty and delicate run of nave arching, and much interest caused by the fact of the church having been rebuilt (originally it was in the eastern portion of the city, where the inhabitants were prevented from attending Mass by reason of the excessive floods) between the years 1402 and 1407—a somewhat remarkable fact of an ancient church having been completed so quickly. It was very unfortunate that the tower arches had been blocked up to support the tower, as opening into this church as they originally did lent great dignity to the edifice.

Lathom's Hospital at Oundle.

At the evening meeting Lord Melville read a paper on the history of Lathom's Hospital—an institution for the reception of eighteen aged women, founded and endowed by the Rev. Nicholas Lathom, rector of Barnwell St. Andrew, in 1597, the income of which is nearly 500*l.* per annum. This hospital, his lordship explained, appears to have been founded on the lines of the old bede-houses which existed before the Reformation, and something upon the system of Browne's Hospital at Stamford. The rules by which the institution was governed were curious. No inmate, for instance, was to be "a common swearer or profane atheist." Those who received benefit from the charity were to go to church whenever the bell rang, "or pay a penny." If any woman were discovered to have been guilty of "sossery" (sorcery) she was "to lose her place forever." Some lessons may be learned from charities dispensed by generations long since passed away. It has been the fashion in modern days to scoff at the charities of past times and the works of the past founder and the dead hand ; but when confronted with the original documents for the establishing of such institutions most right-minded persons will scarcely withhold their meed of admiration at the works of men who have left their footprints on the sands of time, traces of which still remain among us.

Caedmon the Poet.

Canon Rawnsley read a paper on "Caedmon, the first English Christian Poet"—the herdman of Hilda's Abbey at Whitby to whom we owe our very vocabulary, and of whom many authors—from Bede to Stopford Brooke—had written eulogistically. The latter said of him, "He was the first who put into verse the new passions and ideas which Christianity had brought to England." Canon Rawnsley went into details—illustrating his remarks by excellent diagrams—concerning the erection of an Anglo-Saxon cross to the dead poet's memory in Whitby churchyard. This memorial was now in course of erection, and would be a beautiful and lasting tribute to the fame of the father of English verse.

Mr. J. S. Phené read a paper on "The Commercial Importance of Peterborough in pre-Roman Times."

Knights Templars at Gidding.

The Rev. W. M. Noble (Wistow) read a paper on the ecclesiastical association of Little Gidding with the Knights Templars and the gallant soldier who fought in Palestine, and who went down into a nameless grave far from his ancestral home.

The Monk's Stone.

Mr. Mark Bullen referred to the stone said to be erected by Godricus of Crowland over the grave of Abbot Hedda and his eighty-four slaughtered monks. Mr. Bloxam had sought to prove, at a former meeting of the Society, that the stone belonged to a period many years later, and was not a commemoration stone at all, but Dean Ingram, in conducting the 1898 congress around the cathedral, had expressed the conviction that this was the original stone, claiming, moreover, that this opinion was shared by every one whose opinion was worth anything at all. He (Mr. Bullen) could not accept Dean Ingram's contention ; but as the very rev. gentleman had stated that he had good reasons with which to support his argument, he trusted that the congress might be favoured with this same information. If eighty monks and an abbot were buried in that one grave, then, taking the memorial-stone in bulk, it worked out at an extremely small proportion of memorial per monk. There would be about $3\frac{1}{2}$ cubic inches for each monk, and an extra half-inch for the abbot. That proportion would do credit to Her Majesty's Board of Works to-day.

Glatton Church.

On Tuesday many members arranged to share in the excursion. Glatton Church was visited under the guidance of the rector, Rev. Mr. Lea, Rev. W. D. Sweeting, Rev. J. K. Archer, Mr. Traylen, Mr. J. T. Irvine and others. The church dates from 1460, but the remains of an earlier building are still evident, and these indicate the handicraft of the thirteenth century. A little door, which by the kindness of the vicar was taken down to give admittance, leads up to the rood-loft, and from thence to a monk's chamber. The church, as a whole, is both handsome and striking. A good deal of the stonework, both inside and outside the church, belongs quite to the Transition period. The outside of the church is worthy of

notice. There is Early English tracery with Perpendicular work above, and in the windows there is a Decorated moulding added to windows of earlier date. A feature of the church is the fine clerestory, which is carried right through the tower, and the wall of the tower is pierced with Perpendicular windows in perfect accord with the windows of the clerestory. This lends dignity to the church and an unusual richness to the tower. The tower, surmounted with its four griffins similar in character to that on the porch of the parish church at Peterborough, is of Barnack rag stone, and similar in date to Kettering, where the same cusped panelling is much used for decorative purposes.

Little Gidding Nunnery.

Of all the quaint little churches in the district there is none like Little Gidding, remotely situated as it is on the frontier line of Hunts. and Norths., in a silent world of its own. The estate on which the little chapel stands was purchased some time ago by the uncle of Rev. W. Hopkinson, purely out of admiration for Nicholas Ferrar, and it has since descended to the rev. gentleman himself. His uncle found the church had been left by the Puritan assault in a ruined condition; he restored its old oak panelling and pillared arcading, quaint old-world furniture and "dim religious light." The Rev. H. Hilton delivered a panegyric on the life and work of Nicholas Ferrar—a man "of great experience, of boundless opportunities. He was no cloistered monk, a brilliant scholar, a Fellow of Clare, a Cambridge professor, an accomplished traveller and linguist, an acceptable companion to royalty, a keen man of business, a wise administrator, a man of advanced liberal views, an M.P. who had made his mark, the rising hope of his Parliament, let alone a man of considerable means; he throws it all over, retires to Little Gidding, lives the life of a recluse, and founded the religious establishment connected with his name."

Conington and Yaxley churches were afterwards visited. Mr. H. M. Townsend described the interior of the church, remarking that the chancel, which was the oldest part of the church, must have been built about 1240 or 1260. The traceries of some of the windows were very beautiful, particularly the lancet windows in the north chancel aisle. The roof of the church was the original one. At the west end was the "parish fire-engine"—a pole with a double hook, used for pulling down burning thatch. It was by no means uncommon to find such pieces of furniture in churches in the Midlands. Perhaps the most interesting feature in the church was a small stone sculptured in relief in the north transept, representing a heart held between two hands. There are only six similar memorials known in England. Tradition, the vicar stated, represented it to be the heart of William of Yaxley, a celebrated abbot of Thorney, who built and endowed this transept. He directed that his heart should be built in the wall of Yaxley Church, and his body buried at Thorney; and, so far as the former direction went, it appeared to have been carried out, as curiosity led a former vicar to make an examination behind the monument, and there he discovered a small cylindrical wooden box containing inside a human heart, quite perfect, but which crumbled to dust in a few moments. The dust was restored to its former place, and the roughly cut box (which was exhibited) was deposited in a cabinet at the vicarage.

The party called in at Old Fletton churchyard on the way back. The tooled cross outside the church was supposed to be Saxon, but, according to Mr. Lynam, was decidedly Norman.

St. Guthlac and the Devils.

At Tuesday's evening meeting a paper was read by Miss Edith Bradley on "Crowland and the Legend of St. Guthlac." It was illustrated by limelight pictures, which were reproductions of drawings from ancient manuscripts in the Harley collection produced under the supervision of Dr. Birch. Miss Bradley first gave a general description of the abbey and of the bridge from information gleaned from ancient and modern sources, and afterwards confined her attention to brief sketches of the lives of the three men whose careers were directly associated with the abbey—Guthlac, Ingulphus and Thurcytel. The series of slides illustrated the history of Guthlac, and represented his journey to Crowland, his tormenting by the fiends, his release by angelic intervention and his death. One very quaint picture showed Guthlac being carried by the imps up to the gates of heaven and down to the jaws of hell. The mouth of hell was depicted, and the figures therein included two monks, a king and an archbishop. Another picture showed Guthlac thrashing a fiend with a whip, while two or three other fiends looked on with undisguised glee at their ill-looking comrade's discomfiture. In another plate one of the figures was shown to be wearing a pair of spectacles. This, Miss Bradley pointed out, was obviously an anachronism—most likely a practical joke on the part of someone who had tampered with the picture. Dealing with the character of St. Guthlac, the speaker said that he possessed those qualities which had from the eighth to the fourteenth centuries made Englishmen—tenacity of purpose and strength of will. In common with Joan of Arc he believed that he received heavenly guidance in his earthly work. He was an austere ascetic, but in the eighth century, within three years of his death, so great was his spiritual reputation that one of the most magnificent of churches was raised to his memory, and he was spoken of as a saint.

Maxey Church and Parish.

Rev. W. D. Sweeting, M.A., read a paper on "Maxey Church and Parish," in which was carefully traced the history of the parish from the earliest records down to the present day. The first mention of the place was in 1013, but there was no mention of Maxey in Domesday. From 1220 the list of ecclesiastics in the parish was complete, though the name of the first could not be discovered. The vicarage house had always occupied the same site, indeed, all the Mediæval residence had been incorporated in the modern structure. The upper chambers of the present house were formerly used as a granary, and when he (Mr. Sweeting) first went to the parish there were parishioners who could remember having carried corn thereto. Referring to the apparently inexplicable distance of the church from the village of Maxey, Mr. Sweeting controverted the theory that there had formerly been a village around the foot of the church, and that the houses had now disappeared. He explained that in remote times there were three hamlets in the parish—Maxey, Lolham and Nunton—and that the location of the church was due to the desire to place the fabric equidistant from the three. Maxey showed at least three—possibly four—distinct periods of Norman work.

Biggin House.

In a paper on Bury-cum-Hepmangrove, the village which now goes by the simple name of Bury, Mr. A. J. Poulter, of Bury, said that at one time the limits of this manor must have been greater than at present, for it is credited with possessing two churches, one only of them remaining, forming a prominent feature in the landscape, as it stands upon the high ground overlooking the Fen towards Ramsey. If, as probably was the case, the manor of Bury-cum-Hepmangrove extended so far as to include the site of what is locally known as the Biggin, it is here we should look for the church, or rather chapel, for this name Biggin is probably the corruption of the name which the place originally bore. It is recorded that a nunnery at one time existed near Ramsey, which was suppressed. If this were a Beguin establishment—these being very numerous in the Middle Ages—the corruption of this name into Biggin is an easy one, not without precedent elsewhere. But that it was a religious establishment of some kind is an opinion greatly strengthened by the finding of fragments of carved stone which formed part of the mullion of a traceried window of a chapel, which would necessarily form an adjunct of such an establishment. These fragments of an earlier building had been incorporated in the walls of the later one, and dislodged by the destruction which goes on in this as in most other old remains. The suppression of this nunnery, if it were one, must have taken place considerably before the dissolution of monasteries, as this building, judging from its style, must have become a secular building and been adapted to domestic purposes early in the Tudor period. What now remains of the domestic Tudor building which followed the ecclesiastical one are but the outer offices and defences of the main structure; the house itself has long since disappeared. It was designated by a writer of the time as a "handsome pile."

The house itself surrounded by the moat, enclosed within walls and buildings sufficiently strong to be defensive, entrance to the enclosed courtyard was obtained through the door in the outer buildings, and from thence access was obtained to the bridge over the moat, and by this means entrance to the house. What little is known of this house is given in Wise and Noble's History of Ramsey (at pp. 207-209). It appears that Sir Philip Cromwell resided here. A writer in 1787 says, "The seat where he resided was a handsome pile, moated round, and not many years since taken down." Biggin House must have been demolished as early as 1757.

On Wednesday the excursions were resumed.

Woodcroft Castle,

the residence of Baron de Lussan, was the first to be examined. The Rev. W. D. Sweeting briefly described the building and a portion of its history. The castle is at present undergoing rebuilding and renovation, an additional storey being added, there having been only two in the original structure. The boundary wall and the round tower are being left intact, but the interior and roofing construction is being entirely altered. There is a substantial moat encircling the castle, except at the point where the old portcullis and drawbridge originally existed. Mr. Sweeting attributed the building to the latter part of the thirteenth century, and explained that the round tower had probably been utilised as a prison or something of that kind, as there were no means of access to it from the interior of the castle. The small square

trefoiled windows were sufficient evidence to justify the belief that the castle had been constructed under foreign supervision, if not by a foreign master builder or architect. The rev. gentleman briefly referred to one well substantiated incident connected with the place. In 1648 the castle was attacked and besieged. Within the castle was a Dr. Hudson, rector of Uffington, near Stamford, and a few gallant men who made a desperate resistance, but ultimately hauled down their colours on promise of quarter. This was not granted, and Dr. Hudson endeavoured to escape by the tower. His assailants pursued him, however, and the doctor climbed over the battlements of the round tower, and hung by a stone water-spout projection over the moat. His inhuman tormentors hacked at his hands as he hung, and maimed and bleeding he fell with a thud into the moat below. He managed to swim to the side, but only to be despatched with spear and pike. An inspection of the castle, as far as was practicable, then followed.

Helpstone Church.

This was the next building visited. The Rev. W. D. Sweeting pointed out the more particular objects of antiquarian interest, especially drawing attention to the unique octagonal tower and the quaint Mediæval tiles at the foot of the altar rails, several patterns of which are in their original setting, whilst others have been rearranged.

Maxey Church.

The vicar (Rev. W. D. Sweeting) addressed the assembly from an ancient tombstone, and gave an interesting history of the adjacent cottage building, known as the Church Hall, once occupied by a Mr. John Smith, on whose tomb, with Latin inscription, he stood. The building, he said, was undoubtedly of fifteenth-century origin, but had been altered into three separate cottages. He also referred to an undoubted discovery he had recently made on his recognising in a secluded place by the river side a cockpit, the existence of which he was previously unaware. The interior of the church was then inspected, the vicar reading extracts from a paper he had delivered the previous evening at Peterborough. He characterised the edifice as a splendid specimen of architecture, showing three or four distinct periods of Norman work. The tower was evidently by the same master builder as that of Castor Church. There were also some specimens of Early Norman work in that church, similar to which none could be traced in Peterborough Cathedral, which showed pretty conclusively that Maxey Church was erected before the date of the more lordly pile. There were also strong evidences of the previous existence of a Saxon church. He concluded that the magnificent Norman arch at the entrance to the lady chapel was of date about 1367.

The party then visited the vicarage, and were shown several interesting curios, including four quaint iron brands for marking cattle, some specimens of Roman pottery made evidently in the neighbourhood, &c.

Northborough Castle and Church.

The historic castle or manor house and church of Northborough came next. Rev. H. J. Dukinfield Astley described the historical and architectural features of the castle, which is historically interesting from the fact that Cromwell had a liking for the place, and spent a great deal of time there. His supposed suite of rooms are now the rendezous of fowls of the air. His widow is said to have passed her last days in the castle with her daughter Mrs. Claypole. There are some beautiful Norman arches over the entrance to the portion of the building now devoted to the pantry and kitchens; there are also oak panelling and fine oak doors. The entrance to the castle is most imposing, having much fine Norman arch work. Northborough Church was described by Mr. Ashley, who said that in its architecture it exhibits the style of the twelfth, thirteenth and fourteenth centuries, but in each case the building as originally planned was never completed, perhaps because funds fell short, or because each succeeding builder planned so boldly that he was never able to carry out either his own or his predecessors' ideas. It is not only a piece of ancient history displaying the progress of Gothic architecture during those periods, but it is also a monument of disappointed hopes and unfulfilled ambitions. The carved oak choir stalls in Peterborough Cathedral were copied very closely from two examples of dressed stone in that church fixed in the wall at the east end of the south side.

The churches of Peakirk, where the late Norman merges into Early English architecture, and Glinton, which has a long slender spire, were the last seen during the excursion.

The closing meeting of the congress, through the kindness of Mrs. Terrot, was held at Woodstone Manor. The Rev. H. J. D. Astley read a paper on Northborough Manor House or Castle and Northborough Church, which had been visited in the afternoon. He confined his remarks more particularly to the castle, the old residence of the Claypoles. In 1646 John Claypole brought his bride there, she being a daughter of Oliver Cromwell, and only seventeen at the time of her marriage. There was a son by this marriage, but he died young and unmarried, so there the line with Cromwell ends, and no Claypole of the present day can lay claim to direct descendancy from the great Protector. The speaker laid particular stress upon the probable resting-place of the great Cromwell's bones. He argued and deduced, and collected evidence and sifted it, until he became partially convinced that Northborough Church was the spot where Oliver Cromwell's remains lie, or at any rate that there is more evidence to suggest his lying there than anywhere else.

Votes of thanks were passed to all who had made the congress successful.

NEW BOARD SCHOOL, EDINBURGH.

THE new day industrial school in Edinburgh, which has been erected by the School Board for the compulsory treatment of truant children under their care, is now completed, and will be opened on September 6 next. Occupying an airy site in St. John's Hill, where the Holyrood Free Church manse formerly stood, the buildings are in the old Scottish style, and in harmony with the architecture of the old town. The frontage is to the north, and to the rear there is a clear view of Salisbury Crags. From its elevated position the school is well off in the matter of light and fresh air, and is conveniently situated in the Dumbiedykes neighbourhood, whence the majority of the day "prisoners" will probably come. Being a mixed school, there are separate entrances from St. John's Hill for boys and girls, and the interior is appointed in such a way that when necessary the sexes may be taught or disciplined separately or together. The school is substantially built, the masonry being faced with Corncockle stone; the partitions in the interior are of red brick, the lower part being glazed; the staircases are wide and convenient, and the fittings elaborate throughout. On the ground floor is situated the office of the school, where the children will be received on admission, and adjoining there is a small bath-room, which will be used for the purpose of the "first wash." To the right of the entrance are the large play-rooms, divided by a folding partition, so that on certain occasions the rooms may be formed into one large hall. Off these play-rooms are the boys and girls' lavatories, fitted with wash-hand basins, baths, and a hot and cold service. There is also a large plunge bath. For the girls, who will do the washing and cleaning required in the school, there is a commodious wash-house, with boiler and fixed tubs, &c. Order and cleanliness will be scrupulously taught, and provision is made for the observance of strict discipline in this direction for both sexes. In the basement there are the hot-water boilers, one for supplying the baths, another for feeding the water pipes which heat the building, and the third the boiler for supplying water for domestic purposes. Corridors run from one end of the building to the other on the first and second floors. In the former is the scholars' dining hall, which is large, well lighted and cheerful, and is furnished with wooden tables and forms, all of which the occupants will require to keep clean. The kitchen adjoining has a service window communicating with the dining-hall, and is fitted up with a large cooking range and porridge and soup boilers. The scullery and store-rooms open off the kitchen, and are supplied with the necessary utensils, the larders being specially fitted up with galvanised bins for keeping the stores of meal, flour, &c. Other conveniences have been arranged, and all enter from the girls' side of the school. On the other side of the corridor are two classrooms, capable of holding forty children each, and separated by means of a folding partition. They are fitted with substantial folding desks, and are well ventilated. On the same floor are also the board-room, which the officials will also use as a dining-room, the lady superintendent's private room, and the officials' cloak-room and lavatories. The top storey contains a couple of classrooms corresponding to the ones below, a large workroom, which will probably be fitted up as a joinery, and other spare rooms, in which will be carried on any other industry, such as mat-making, which the Board may prescribe. The janitor's house is also on this flat. Altogether the school seems admirably adapted for the purpose the Board have in view. The building has been properly appointed, and is thoroughly ventilated by the extract system, the ventilating fan being driven by a gas-engine. As yet there is nothing to relieve the monotony of the bare walls, but three interesting relics of the old manse have been rescued and placed in the corridors. They are frescoes of rustic scenery, and are supposed to be the work of Nasmyth. Outside are large concreted playgrounds and offices. Mr. Robert Wilson, architect, Queen Street, designed the buildings, which were erected by Mr. James Kinnear, builder. The cost of the building, which is certified to accommodate 160 scholars, is a little over 9,000*l.*, and the price of the site about 2,000*l.*—together over 11,000*l.*

TESSERÆ.

Michel Angelo as a Colourist.

FRESCO, which does not admit of that refined variety of tints that are the privilege of oil painting, and from the rapidity with which the earths, its chief materials, are absorbed, requires nearly immediate termination, is for those very reasons the immediate minister and the aptest vehicle of a great design. Its element is purity and breadth of tint. In no other style of painting could the generic form of Michel Angelo have been divided, like night and day, into that breadth of light and shade which stamps their character. The silver purity of Correggio is the offspring of fresco; his oil-paintings are faint and tainted emanations of the freshness and "limpidezza" in his frescoes. The master of the colour we see in the Sistine Chapel could have no other, for though colour be the least considerable of that constellation of powers that blaze in its compartments, it is not the last or least accomplishment of the work. The flesh of the academic figures on the frames of the ceiling is a flesh even now superior to all the flesh of Annibale Carracci in the Farnese, generally pale though not cold, and never bricky though sometimes sanguine. The "Jeremiah among the Prophets" glows with the glow of Titian, but in a breadth unknown to Giorgione and to him. The "Eve under the Tree" has the bland pearly harmony of Correggio, and some of the bodies in air on the lower part of the "Last Judgment," less impaired by time or accident than the rest, for juice and warmth may still defy all competition. His colour sometimes even borders on characteristic variety, as in the composition of the "Brazen Serpent." That a man who mastered his materials with such power did reject the certain impediments and the precarious and inferior beauties of oil, which Sebastian del Piombo proposed for the execution of the "Last Judgment," and who punished him for the proposal with his disdain for life, cannot be wondered at. The object of admiration in Michel Angelo's colour is the tone, that comprehensive union of tint and hue spread over the whole, which seems less the effect of successive labour than a sudden and instantaneous exhalation, one principle of light, local colour, demi-tint and shade. Even the colours of the draperies, though perhaps too distinct, and often gayer than the gravity of their wearers or the subject allowed, are absorbed by the general tone, and appear so only on repeated inspection or separation from the rest. Raphael did not come to his great work with the finished system, the absolute power over the materials, and the conscious authority of Michel Angelo. Though the august plan which his mind had conceived admitted of lyric and allegoric ornament, it was upon the whole a drama and characteristic; he could not, therefore, apply to its mass the generic colour of the Sistine.

Canons of Proportion.

There is no form, perhaps, in nature which admits of such variety, both in appearance and proportion of parts, as the body of man, and which therefore seems so little capable of being reduced to any definite system of proportion. The proportions of the form of the infant are different from those of youth, these again from those of manhood, and these again perhaps still more from those of old age and decay. If there were any instinctive sense of beauty in form in this long history there would be one age only in which this sense could be gratified. Yet everyone knows not only that each of these periods is susceptible of beautiful form, but what is much more, that the actual beauty in every period consists in the preservation of the proportions peculiar to that period, and that these differ in every article almost from those that are beautiful in other periods of the life of the same individual. The same observation is yet still more obvious with regard to the difference of sex. In every part of the form the proportions which are beautiful in the two sexes are different, and the application of the proportions of the one to the form of the other is everywhere felt as painful and disgusting. If, however, there were any original and essential beauty in some definite proportion of parts, such effects could never happen. This definite proportion in every case would be solely beautiful, and every variation from it would affect us as a deviation or opposition to the genuine form of beauty. It may be observed, in the same manner, that if the beauty of form consisted in any original proportion, the productions of the fine arts would everywhere have testified it, and that in the works of the statuary and the painter we should have found only this sole and sacred system of proportion. The fact, however, is (as everyone knows) that in such productions no such rule is observed; that there is no one proportion of parts which belongs to the most beautiful productions of these arts; that the proportions of the Apollo, for instance, are different from those of the Hercules, the Antinous, the Gladiator, &c.; and that there are not in the whole catalogue of ancient statues two perhaps of which the proportions are actually the same. Against the hypothesis of an instinctive beauty in proportion no fact can be so decisive as this. If here were any original beauty in peculiar proportions of the human form the artists of antiquity must have perceived it, when it was so easy a matter to ascertain it only by the labour of measurement and calculation; and that their productions are independent of such definite proportions, and that their effect is still produced amid all this variation of proportion, are irrefragable proofs not only that the beauty of their works is not dependent upon such a theory of proportion, but that it arises from some higher causes and from some more profound attention to those feelings of human nature in which the sentiment of beauty is to be found.

The Theban Corinthian Order.

In the church of St. Demetrius at Thebes may be seen several beautiful capitals of that most ancient pattern of the Corinthian order which is entirely without volutes at the corners, and has a single wreath of the simplest acanthus foliage to crown its base. It is only known to those persons who have seen the very few examples of it which exist among the ruins of the Grecian cities. There is no trace of it among the remains at Rome, yet in point of taste it is so exceedingly superior to the more ornamented and crowded capitals which were afterwards introduced, that both the rival *connoscenti* at Athens, Lusieri and Fauvel, have drawn and modelled it, and they have spoken of its discovery as forming an epoch in the history of art. In one or two instances the attention of the ancient sculptor to simplicity has been so severe that even the edges of the foliage have not been ruffled, but expressed in gross; and consequently the admirers of excessive minuteness in the detail of little parts will call such capitals unfinished, although the grandeur of design, when viewed at the distance in which such objects were intended to be seen, especially in the majestic temples of Greece, be thereby considerably augmented. It is to this cause that the Doric, in buildings of so much vastness, owes its superiority over all other orders of architecture; to that simplicity which is the very soul of grandeur, where nothing that is little can be tolerated for an instant. Excessive minuteness of design may suit the puny imitation of Grecian architecture seen in the buildings of modern cities, upon the same principle that it is allowable in a piece of Chinese carving in ivory, because works of this kind are intended for a small scope of observation, but when such minuteness is introduced into the vast features of a gigantic style, it becomes superfluous and contemptible.

Symbols on Tombs.

The Greeks, instead of the inscription, sometimes engraved the instruments of the profession of the defunct; often, also, emblems which marked their temper and character, or symbols and figures of that which they liked best. To heroes they raised tombs of superior execution, in which they placed their ashes, and put upon them a column bearing the marks and symbols of the deceased. The instructions which Trimalchio, in Petronius, gives for the bas-reliefs of his own tomb, and the immense collection of Boissard, show that the Romans followed these rules and lead to an inference that such sepulchres are subsequent to the Roman conquest of Greece. The pretended monument of the Curiatii, consisting of a square base supporting one large cone in the middle and four others smaller, one at each angle, was probably a much earlier fashion, for a pyramid was placed on the top of the celebrated mausoleum of Artemisia. The bas-reliefs upon tombs were sometimes arbitrary, but frequently had a meaning complimentary to the deceased. Trimalchio desires that the likeness of his dog may be formed at the feet of his statue, and the monument be adorned with garlands and representations of the combats which should take place at his funeral. Upon the monument was to be carved a ship under full sail to show that he obtained his wealth as a merchant, in which ship he should be represented sitting, clothed in magisterial robes and insignia, pouring out riches upon the multitude; also a triclinium, and the people feasting therein. At his right hand was to be placed his wife Fortunata, with a Sicilian dove, and holding a dog by a chain, also amphoræ well secured, while one was to appear broken and upon it a boy weeping for the misfortune. The whole was to be surmounted by a sun-dial, that the eye of the traveller, willing or unwilling, might be attracted to the inscription recording his name. Elpenor says to Ulysses, "Put an oar upon this sepulchre with which I used to row with my companions," and though many decorations of tombs were capricious, yet there are some which may be considered as symbolical.

Cyclopean Walls.

The general character of the Cyclopean style is immense blocks without cement, and though the walls are now irregular, from smaller stones which filled up the interstices having disappeared, yet they were once so compact as to seem an entire mass. The stones at the foundation were smaller than those above. Schneider, editor of "Vitruvius," contends that the style called by that author "insertum" does not mean small stones thrown into cement, but large stones, among which smaller

were inserted—a style called "antiquum" also by Vitruvius because it was the most ancient manner of building. Hamilton divides the style into four periods, viz. the first or oldest is that used at Tiryns and Mycenæ, consisting of blocks of various sizes, of which the interstices are or were filled up with small stones. The second, as at Iulis and Delphi, is marked by polygonal stones, which nevertheless fit into each other with great nicety. In this style there are no courses. The third, as in the Phocian cities, and in some of Bœotia and Argolis, is distinguished by the work being made in courses, and the stones, though of unequal size, being of the same height. The fourth and youngest style presents horizontal courses of masonry, not always of the same height, but formed of stones, which are all rectangular. This style was chiefly confined to Attica. Tiryns is the first-known specimen of military architecture or improvement upon earthworks, for Pliny says that the Cyclops are affirmed to have been the inventors of the fortifications of towns and also of towers in these identical instances, of Tiryns and Mycenæ. Sir William Gell adds that Tiryns is the best specimen of the military architecture of the heroic ages. Homer calls it the well-walled Tirynthus.

Invention in Painting.

The invention of a painter consists not in inventing the subject, but in a capacity of forming in his imagination the subject in a manner best accommodated to his art, though wholly borrowed from poets, historians or popular tradition. For this purpose he has full as much to do, and perhaps more, than if the very story was invented, for he is bound to follow the ideas which he has received, and to translate them into another art. In this translation the painter's invention lies; he must in a manner new-cast the whole, and model it in his own imagination; to make it a painter's nourishment it must pass through a painter's mind. Having received an idea of the pathetic and grand in intellect, he has next to consider how to make it correspond with what is touching and awful to the eye, which is a business by itself. But here begins what in the language of painters is called invention, which includes not only the composition or the putting the whole together, and the disposition of every individual part, but likewise the management of the background, the effect of light and shadow and the attitude of every figure or animal that is introduced or makes a part of the work. Composition, which is the principal part of the invention of a painter, is by far the greatest difficulty he has to encounter. Every man that can paint at all can execute individual parts, but to keep those parts in due subordination as relative to a whole requires a comprehensive view of the art, that more strongly implies genius than perhaps any other quality whatever.

Plant Forms and Ornament.

There appears to be no form which is peculiarly or solely beautiful, and as in winding or curvilinear forms the general nature of language seems to ascribe this beauty to their expression of delicacy and not to the mere circumstance of form itself, it appears probable that the beauty of such forms arises from this expression and not from any original fitness in such forms to excite this emotion. When winding or curvilinear forms cease to be expressive of tenderness or delicacy it will be found that they cease also to be felt as beautiful. The greater part of beautiful forms in nature are to be found in the vegetable kingdom, in the form of flowers, of foliage, of shrubs and in those assumed by the young shoots of trees. It is from them, accordingly, that almost all those forms have been imitated which have been employed by artists for the purposes of ornament, and whoever will take the trouble of reviewing the different ornamental forms will find that they are almost invariably the forms of such vegetables or of such parts of vegetables as are distinguished by the delicacy and tenderness of their texture. There are many parts, however, of the vegetable kingdom which are not distinguished by this character of delicacy. The stem of some species of flowers and of almost all shrubs, the trunk and branches of trees, are distinguished by opposite characters and would indeed be unfit for the purposes of vegetation if they were not. In these subjects, accordingly, the winding or serpentine form is very far from being beautiful, as it has no longer its usual expression of fineness or delicacy. In the smaller and feebler tribe of flowers, for instance, as in the violet, the daisy or the lily of the valley, the bending of the stem constitutes a very beautiful form, because we immediately perceive that it is the consequence of the weakness and delicacy of the flower. In the rose, on the contrary, and the white lily, and in the tribe of flowering shrubs, a class of vegetables of greater strength, the same form assumed by the stem is felt as a defect, and instead of impressing us with the idea of delicacy leads us to believe the operation of some force to twist it into this direction. In the young and feeble branches of such plants, however, this form is again beautiful, when we perceive that it is the consequence of the delicacy of their texture and of their being overpowered by the weight of the flower. In the vine or ivy, in the same manner, the winding of the young shoots and feebler branches constitutes very beautiful forms. In the direction of the stem, on the other hand, such forms are felt as a defect, as no longer expressive of delicacy, but of force. In the growth of the stronger vegetables, as of trees, where we know and expect great strength, nothing can be so far from being beautiful, as any winding or serpentine form assumed by the trunk. The beautiful form of such objects is of so very different a kind that it is in the opposite form only that we perceive it. In the direction of the branches the same character is expected, and a similar defect would be felt in their assuming any regularly winding or curvilinear form. It is only when we arrive at the young shoots, and that only in their infant season, in spring, that we discover again the serpentine form to be beautiful, because it is then only that we perceive it to be really expressive of tenderness or delicacy. Observations of this kind are within every person's reach, and it will be found that in the vegetable kingdom the winding or serpentine form is no longer beautiful than while it is expressive of some degree of delicacy or fineness, and that it ceases to be beautiful whenever it is assumed by bodies of a different kind.

Sandro Botticelli.

Sandro was a man of singularly inventive genius and endowed with an ardent and highly poetic temperament, which often betrayed him into an excess of phantasy. But the sense of life which glows through all his productions extenuates the frequent fault of over-vehement action in his figures. If he seldom attained the dignity of his master, Fra Filippo Lippi, in pose, and generally fell short of him in majesty and simplicity of drapery, as well as in refinement of colour, he nevertheless reached a high degree of excellence in both of these last qualities. Where Fra Filippo was all repose Sandro was all movement. His range of subjects was immense, according to the calls of his patrons and the untamable energy of his own nature. It extended from great scriptural compositions, as in his frescoes in the Sistine Chapel and large altar-pieces treated with great power, through the most touching scenes in the life of the Virgin, to events in classic history, including allegorical and mythological subjects. All these he treated in a form which was the natural outcome of the Renaissance, but with a verve, naïveté and pathos peculiar to himself. He was a profound student of Dante, whose "Divine Comedy" he illustrated, and even annotated; and there can be little doubt that the "Convito" was suggestive to him in many of his conceptions. He became a follower of Savonarola, and no doubt suffered from it. The contemporaneous reputation of Botticelli stood high, and Vasari reckons him as the best painter in Florence on the death of Fra Filippo. The same writer makes him the instructor of Filippino Lippi. Having been a man of careless habits as regards money, and erratic in his work, he finally fell into a state of poverty, and was supported in his declining days by the Medici and other friends until his death, May 17, 1510. He was buried in a tomb, constructed by his father, in the church of Ognissanti, Florence. His extant works are numerous, although many bearing his name can only be considered as having issued from his *bottega*.

Merton College Glass.

The glass in Merton library, Oxford, exhibits a mixture of Decorated and Perpendicular features. For instance, the character of the borders of the lights is Decorated, and the "smear shading" of the Agnus Dei is a Decorated feature; whilst the smooth and even tint of the ruby, and the thinness of its colouring matter (which will easily be perceived on a close examination of the circle containing the Agnus Dei on the red ground), and the design of some of the quarries, as clearly characterise the Perpendicular style.

CITY IMPROVEMENTS.

At the meeting of the Court of Common Council on the 21st inst., the finance and improvements committee submitted for approval a plan for continuing the improvement of Fleet Street by making it 60 feet wide westward of St. Dunstan's Church to the City boundary. They recommended that on the London County Council signifying its intention of contributing half the net cost of carrying out that section of the improvement, notice be served to acquire the ground needed in front of Messrs. Gosling's bank, and that they (the Corporation) be authorised to take the necessary steps for taking back the other premises as opportunities occurred. The report was approved.

A report was presented from the City lands committee enclosing a letter from the Secretary of State for the Home Department, stating the terms upon which Her Majesty's Government would co-operate in the scheme for the rebuilding of the Sessions House, Old Bailey. The Government would be ready to hand over to the Corporation the male wing of

Newgate Prison in consideration of the sum of 40,000*l.* No demand would be made on the Corporation to provide prison accommodation in lieu of that wing or to provide extra cells at Holloway, but some sleeping cells and a kitchen should be added to the new Sessions House. The committee in their report asked the Court of Common Council to sanction the proposal set forth in the letter, and to refer the matter back to them to carry into execution.

Mr. Baddeley, the chairman of the committee, said it was a source of great gratification to know that after twenty years' negotiation with successive Governments they had got from the present Government this very good offer. They were now within measurable distance of having a Sessions House worthy of the City of London.

Mr. Alderman Alliston congratulated the committee upon the successful result of their negotiations. He hoped that the new Sessions House would be a credit to the City, because the administration of justice was not only one of the duties, but one of the privileges of the Corporation.

The report was agreed to, and the Court adjourned for the vacation.

NEW THEATRE FOR KENNINGTON.

ON the 25th inst. Sir Henry Irving laid the commemoration stone of the new theatre which is in course of construction in the Kennington Park Road, on the site which was once occupied by the palace of the Bishops of Rochester. The Princess of Wales Theatre, as this new temple of the drama is to be designated, has been designed by Mr. W. G. R. Sprague, and will occupy an excellent site, having frontage of about 80 feet to Kennington Park Road, 130 feet to South Place, 90 feet to De Laune Street.

The whole of the main frontage will be executed in white Portland stone. The elevations are of rich Italian Renaissance character. The more expensive parts of the house will be entered from Kennington Road by a few broad steps running the entire length of the 50 feet wide stone colonnade, into a vestibule or lobby, and thence to the grand crush-room. This apartment will be one of the features of the building, having a length of 42 feet and a width of 22 feet. The wall will be of a specially selected Italian marble and recessed marble columns will add to its beauty, whilst specially designed and deeply recessed fireplaces at each end will enhance the general effect of comfort and luxury. From this crush-room ascends a bold marble staircase 27 feet wide, branching off on each side to the dress circle, with a separate entry to each side of the stalls.

Directly above the main crush-room will be a ladies' foyer and the grand saloon, both of those apartments being quite separate and treated in the same rich style of decoration. The ornamentation throughout the interior will be French Renaissance with a free introduction of paintings on ceilings and panellings, whilst the draperies and colourings throughout will be of harmonious and soft tints with a free use of gold, so that the utmost effect of richness and harmony may be obtained without the making of any one colour obtrusive.

The auditorium, constructed on the cantilever system without a single pillar to obstruct the view from any part of the house, will have an average depth of 70 feet and a clear width of 60 feet. It is arranged in two tiers, viz. stalls, pit-stalls and pit on the ground-floor, dress-circle forming the first tier or balcony, and the gallery and amphitheatre being the second tier. The decorations of the auditorium throughout will be rich and the electric light will be employed in the scheme of decoration.

Exceptionally large and richly-decorated saloons are adjacent to each part of the theatre, the pit-saloon having the walls entirely covered by fancy tiling. The lavatory accommodation has received special care, and will be as perfect as modern science can make it. In every case the walls are lined with white or fancy tiles. The gallery staircase and pit entries and exits, &c., will be lined with white or other glazed bricks.

The theatre throughout will be heated and ventilated on the plenum system, and fresh air of the required temperature will be distributed by flues and channels to the different parts, the foul or used-up air being gently forced through powerful exhausts. A complete set of hydrants and fire appliances is arranged, and the stage will be fitted with a special double steel and asbestos fireproof curtain, controllable by one man. The stage will be about 80 feet wide and 50 feet deep. The electric light will be generated by steam plant, and will be of sufficient power to give any possible electrical stage effects without diminishing the other lighting of the house, &c. The dressing-rooms are numerous, are fitted with all the latest sanitary appliances, are heated throughout and well ventilated, and are entirely separated from the stage by stout brick walls and iron doors. Large scenery stores, painting-rooms, property-rooms, &c., are all included in the scheme.

As giving some idea of the thoroughly up-to-date nature of the structure, it should be mentioned that the iron girders which support the upper parts of the auditorium on the cantilever system, are the largest that have been used in any theatre in the country.

The contractors are Messrs. Walter Wallis & Co., contractors, Balham.

For this new playhouse South Londoners are indebted to the enterprise of Mr. Robert Arthur, who, if not already well known in the Metropolis, has achieved a well-deserved reputation in the provinces, where the limited liability company of which he is the chief manages the theatres at Aberdeen and Dundee, the Royal, Newcastle, Royal Court, Liverpool, and Royal, Nottingham, the Kennington Theatre is entirely a private enterprise of Mr. Arthur's, who has also secured the English rights of M. Messager's new opera, "Les Petites Michu," which he expects to produce at a West-end theatre at no distant date.

GENERAL.

Mr. A. G. Temple, F.S.A., director of the Corporation Art Gallery, has received the decoration of Officier de l'Instruction Publique, in commemoration of the exhibition of the French art collection at Guildhall and the hospitality extended to French art and artists in connection with it.

The Municipality of Malo-les-Bains have offered prizes of 500 francs, 300 francs and 200 francs for the best designs for a "poster" suggestive of the attractions of the watering-place.

The Late Mr. Nicholas Carter, the first mayor of Harrogate, granted to the Corporation at a nominal price, about fourteen years ago, about two acres of building ground in the centre of the town for a town-hall. His intention was never realised. It is now urged that the Corporation should fulfil the trusts of the bequest.

Mr. C. T. Part has resigned his seat on the Herts County Council. In his letter he says, "It appears that although I may sell road material to the highways committee, of which I am a member, I may not be a partner in a bank which has the account of the asylums committee, of which I am not a member."

The Edinburgh School Board have decided to erect three new schools. The sites selected are at Comely Bank, in the north-western part of the city, New Market Street and Parson's Green. The cost will probably be from 70,000*l.* to 75,000*l.*

The Prize Distribution at the Royal College of Art, South Kensington, which was to have taken place on July 29, has been postponed.

A Museum of Casts from Antique Sculpture has been opened in the Louvre. The riding school of the late Prince Imperial has been appropriated to accommodate it.

A Design by Herr Thiersch has been adopted for the German palace at the Paris Exhibition of 1900.

The Final Meeting of the British Commission for the Brussels International Exhibition has been held. It was reported that the gross surplus remaining out of the Government grant of 5,500*l.* was 2,475*l.* 7*s.* 8*d.*, and the net surplus, after meeting certain appropriations, was upwards of 700*l.* It was resolved to authorise the treasurer, Sir Edward H. Carbutt, to remit this amount to the Chancellor of the Exchequer.

M. Lucien Merlet, the French archæologist, has died in Chartres in his seventy-second year. He was the author of several works, and besides served the State as keeper of archives.

M. Bourgeois, the French Minister of Public Instruction, in opening the new galleries of the Jardin des Plantes congratulated M. Dutert, the architect, and M. Cormon, the painter.

The New Synagogue in Strassburg, which is approaching completion, was designed by Professor Ludwig Levy, of Carlsruhe.

Mr. Hamo Thornycroft, R.A., has visited Dublin to consider question of site and other subjects connected with the statue of the late Lord Plunket, archbishop of the diocese.

The Hope Collection has been disposed of to Mr. Wertheimer for the sum of 121,550*l.* There are eighty-three pictures by Dutch and Flemish artists. Five years ago the collection was valued at 80,000*l.*

The Lord Provost's committee of the Edinburgh Town Council have recommended the Council to approve of the elevation and plans for the southern portion of the site in North Bridge Street, purchased by the Commercial Bank of Scotland, Limited.

THE

Architect and Contract Reporter.

IMPORTANT NOTICE.

WORKMEN'S COMPENSATION ACT.

In view of the many difficulties which are certain to arise in connection with the law, practice rules and procedure under the above Act, we have added to our staff A VERY EMINENT BARRISTER, who has made the subject a special study, and will be glad to answer in the columns of this paper any questions relating to the complicated matters arising from the provisions of this difficult Act. Our LEGAL ADVISER will further answer any legal question that may be of interest to our readers. All letters must be addressed "LEGAL ADVISER," Office of "The Architect," 175 Strand, London, W.C.

EDITORIAL NOTICES.

The authors of signed articles and papers read in public must necessarily be held responsible for their contents.

No communication can be inserted unless authenticated by the name and address of the writer—not in every case for publication, but as a guarantee of good faith.

Correspondents are requested to make their communications as brief as possible. The space we can devote to Correspondence will not usually permit our inserting lengthy communications.

TENDERS, ETC.

*** *As great disappointment is frequently expressed at the non-appearance of Contracts Open, Tenders, &c., it is particularly requested that information of this description be forwarded to the Office, 175 Strand, London, W.C., not later than* 2 P.M. *on Thursdays.*

NEW READING CASE.

To Librarians of the Public Libraries and Reading-rooms.—A new handsome Reading Case can be supplied at a nominal charge of 2s., by post 2s. 6d., on early application to the Publisher, 175 Strand, W.C.

For Advertisement Scale, see page xiii.

COMPETITIONS OPEN.

BIRMINGHAM.—Designs for manufacturing buildings, area 3,000 square yards, with basement, sub-basement and four or five storeys, in Birmingham. Particulars from Mr. H. L. Müller, Birmingham.

GLASGOW.—Aug. 15.—Designs are invited for the exhibition buildings to be erected on sites in the Kelvingrove Park and Bunhouse Ground. A premium of 200*l.* will be awarded to the author of the design considered first in merit, second and third premiums of 150*l.* and 100*l.* respectively. Mr. H. A. Hedley, general manager and secretary, 141 Buchanan Street, Glasgow.

LEAMINGTON.—Free library and institute. 100 guineas (merged), 50 guineas. Particulars from Mr. H. Consett Passman, town clerk, Leamington.

LIVERPOOL.—Oct. 3 (time extended).—Designs for new buildings for Royal Institution. 50 guineas, 20 guineas. Mr. Harold Waterhouse, hon. sec., 3 Cook Street, Liverpool.

PLYMOUTH.—Buildings in Tavistock Street (250*l.*). Particulars from Mr. J. H. Ellis, town clerk, Plymouth.

ROTHERHAM.—Plans are invited for proposed extensions of the Baptist schoolroom, Westgate, Rotherham, at a cost of about 600*l.* Mr. A. Crowcroft, Clifton Crescent South, Rotherham.

SALFORD.—Aug. 16.—Designs for three chapels, offices, lodge, entrance gates and boundary walls at proposed cemetery in Langley Road and Agecroft Road, Pendlebury. Premiums of 50*l.*, 30*l.* and 20*l.* respectively. Borough Engineer, Town Hall, Salford.

STOCKHOLM.—Aug. 31.—Designs for railway station Particulars from the Offices of the Consulate, 27 Great Winchester Street, London.

CONTRACTS OPEN.

ABERDEEN.—Aug. 5.—For erection of a parish church hall, Kintore. Mr. Roger, session clerk.

ABERDEEN.—For erection of a cottage at Glasgoego, Blackburn. Mr. James Kemp, 621 George Street, Aberdeen.

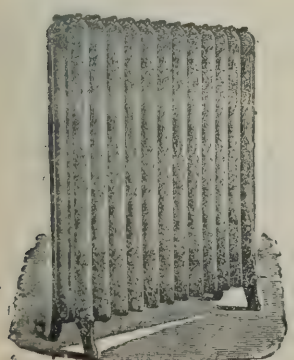
ALDERLEY EDGE.—Aug. 2.—For erection of a generating station and electric-lighting works at Belmont. Mr. W. E. Rowcliffe, 30 Cross Street, Manchester.

BATLEY CARR.—Aug. 8.—For erection of a branch store in Warwick Road. Messrs. Holtom & Fox, architects, Northgate, Dewsbury.

BEXHILL.—Aug. 15.—For erection of boundary-walls, railing, kerbing, paving and channelling the footpaths and other works opposite the town hall. Mr. Geo. Ball, surveyor, Town Hall, Bexhill.

BLETCHLEY.—Aug. 2.—For erection of two cottages and a shop, with alterations to existing shop, in Albert Street. Mr. A. E. Wade, 1 Albert Street, Bletchley.

BRADFORD.—Aug. 4.—For erection of a store and five houses in Gilpin Street, Barkerend Road. Messrs. Rycroft & Firth, architects, Bank Buildings, Manchester Road, Bradford.



BRADFORD.—Aug. 4.—For erection of eleven through houses, Newburn Road, Great Horton. Mr. Sam. Spencer, architect, 244 Great Horton Road, Great Horton, Bradford.

BRIDGEND.—Aug. 2.—For erection of closets and lavatories to the Pontyrhyl Board schools. Mr. D. Edmonds, clerk, Bettws.

BRIDLINGTON QUAY.—Aug. 2.—For alterations and additions to Carnaby House and premises. Mr. J. Earnshaw, architect, Wellington Road, Bridlington Quay.

BRIGHTON.—Aug. 2.—For alterations and additions to the gentlemen's cloakroom and lavatory at the Royal Pavilion. Mr. Francis J. C. May, Town Hall, Brighton.

BRISTOL.—Aug. 6.—For erection of a police-station at Staple Hill, near Bristol, for the Gloucestershire Standing Joint Committee. Mr. M. H. Medland, architect, 15 Clarence Street, Gloucester.

BERRY, CAMPBELL & CO.

WARMING & VENTILATING ENGINEERS,

62 WATLING STREET, QUEEN VICTORIA STREET.

Heating by Hot Water, or High or Low Pressure Steam, expeditiously carried out on the most approved principles. Special attention given to Private Residences.

ESTIMATES FREE.

BURNLEY.—Aug. 13—For erection of imbecile wards in the grounds of the workhouse. Mr. S. Keighley, architect, Nicholas Street, Burnley.

BURY.—For erection of premises for the *Bury Guardian* Company, Limited. Mr. Alfred Hopkinson, architect, 15 Agur Street, Bury.

CAMBERWELL.—For alterations and additions to the Manor Laundry, George Street. Messrs. Johnstone Bros., architects, 39 Lowther Street, Carlisle.

CARDIFF.—Aug. 3.—For erection of an infants' school, manual instruction centre and other work at Severn Road school. Messrs. J. P. Jones, Richards & Budgen, architects, 18 St. Mary Street, Cardiff.

CHOLLERTON.—Aug. 3—For additions and alterations to the Chollerton parochial schools. Right Rev. Bishop W. B. Hornby, Chollerton.

CLACTON-ON-SEA.—Aug. 6.—For erection of a cottage hospital. Mr. J. W. Martin, architect, Station Chambers, Clacton-on-Sea.

CLAYTON.—Aug. 2.—For alterations, &c., to the wash-house and laundry at the workhouse. Mr. Sam Spencer, architect, 344 Great Horton Road, Great Horton, Bradford.

COLNE.—Aug. 3.—For erection of Board schools on the Park site. Mr. H. Holgate, architect, Market Street, Colne.

CONSETT.—Aug. 31—For erection of the new institute buildings in Park Road, Consett. Messrs. Plummer & Burrell, architects, 13 Grey Street, Newcastle-upon-Tyne.

DEVONPORT.—Aug. 4.—For erection of a rectory house at Stoke Damerel. Mr. W. D. Caroe, 8A Whitehall Place, London, S.W.

DEVON.—Aug. 4.—For repairs to house and buildings at Forda Farm, Ashwater. Messrs. Thompson & Co., surveyors, 24 Gandy Street, Exeter.

DEVONPORT.—Aug. 4.—For erection of an additional storey to the workhouse infirmary, for the Guardians of Stoke Damerel. Mr. H. G. Luff, architect, 64 Chapel Street, Devonport.

DONCASTER.—Aug. 3.—For erection of an isolation hospital adjoining Common Lane, Balby. Mr. William H. R. Crabtree, borough surveyor, 3 Priory Place, Doncaster.

ELGIN.—Aug. 1.—For erection of an hotel and offices at Archiestown. Mr. James Jamieson, architect, Elgin.

ELGIN.—Aug. 2.—For erection of refreshment-room at the Elgin Auction Mart. Mr. Charles C. Doig, architect, Elgin.

FOLESHILL.—For erection of three dwelling-houses, Lockhurst Lane. Mr. T. F. Tickner, architect, 7 Bishop Street, Coventry.

GILDERSOME.—Aug. 3.—For alteration and addition to Street Lane Board schools. Messrs. Buttery & Birds, architects, Queen Street, Morley.

GLOUCESTER.—Aug. 15.—For erection of infectious diseases hospital and buildings in connection therewith at Over. Messrs. Evans & Son, 7 John Street, Adelphi.

HALIFAX.—Aug. 6.—For erection of caretaker's house, for Halifax Cricket and Football Club. Mr. Medley Hall, architect, 29 Northgate, Halifax.

HALIFAX.—Aug. 12.—For alterations and additions to Pioneer Tool Works. Mr. Medley Hall, architect, 29 Northgate, Halifax.

HALIFAX.—Aug. 11.—For erection of a house, shop and offices, West Vale. Mr. W. Clement Williams, architect, 29 Southgate, Halifax.

HAMMERSMITH.—Aug. 4.—For distempering and other works at the infirmary, St. Dunstan's Road. Mr. T. Aplin Marsh, 75 Fulham Palace Road, Hammersmith, W.

HAMPTON WICK.—Aug. 3.—For repairs and painting offices and lamp standards generally, for the Hampton Wick Urban District Council. Mr. J. Nixon Horsfield, surveyor, Hampton Wick.

HANDSWORTH.—Aug. 8.—For erection of new schools at Woodhouse (West). Mr. John D. Webster, architect, Cairns Chambers, 19 St. James's Street, Sheffield.

HEREFORD.—Aug. 2.—For enlargement of the main room of Letton School. Rev. R. Bishop, Letton Rectory, Hereford.

HUDDERSFIELD.—Aug. 2.—For erection of three shops, Station Road. Mr. J. Berry, architect, 9 Queen Street, Huddersfield.

ILKLEY.—Aug. 9.—For erection of a block of three villas. Messrs. Isitt, Adkin & Hill, architects, Prudential Buildings, Bradford.

IRELAND.—Aug. 1.—For alterations and additions to Drumragh Catholic church, and for erection of a caretaker's residence. Mr. James L. Donnelly, architect, 8 Castle Street, Omagh.

PRICE LIST AND ESTIMATES ON APPLICATION.

PATENT

VULCANITE ROOFING.

Since the introduction of the patent Vulcanite Roofing into this country it has been adopted by a great number of leading architects for Public and Private Buildings, Hotels, Schools, Hospitals, Theatres, Mills, Warehouses, Breweries, Shops, Villas, Dwelling-houses, &c.

The temperature of the rooms immediately beneath the roof is more even in winter and summer than under any other roof. When properly laid repairs are never required, and all roofs are guaranteed. The roof-surface can be used as a garden, or for any other purpose. The cost of construction is less than even for a slate or tiled roof.

SHEET ASPHALTE for DAMP-COURSE, WATERPROOFING VAULTS, BRIDGES, TUNNELS, &c., is manufactured ready for use in lengths of 40 feet, and any width up to 40 inches, being more convenient than the usual damp-course slabs, and saving laps. Price lower and quality much superior to any similar article in the market.

SHEET ASPHALTE for ROOFING SHEDS, LIGHT BUILDINGS, &c., and for SARKING under slates or tiles, manufactured in five different qualities and in rolls of 15 superficial yards. It is easily laid, very inexpensive, much superior to felt roofing, and requires no annual coating.

Full particulars, Catalogues, Detail Sketches, Estimates, re Vulcanite Roofing; Samples, Prices, &c. re Sheet Asphalte, free.

THE PATENT VULCANITE ROOFING & ASPHALTE CO., LTD.,

28 VICTORIA STREET, WESTMINSTER, LONDON, S.W.

Inquiries from the North of England, Scotland, and Ireland, please address to Laganvale, Belfast.

Agents wanted in all districts where not yet represented for laying of Vulcanite Roofs and Sale of Sheet Asphalte.

ELECTRIC NOTES.

A LOCAL company intends to erect works for the purpose of supplying electricity in the district of Fleet, Hants, the present illumination being by oil. Mr. F. J. Warden-Stevens has been retained to act as consulting engineer for the scheme.

AT the monthly meeting of Greenock Police Board a letter was submitted from the North British Electricity Supply Company, Limited, intimating their intention to again apply for a Provisional Order for the burgh of Greenock on or before December 21. The letter was remitted for consideration.

THE City of London Electric Lighting Company's gross revenue for the quarter ending June 30 was 28,126*l.*, against 26,158*l.* in 1897. In making a comparison it must be remembered that since the commencement of 1898 the reduced charges of 7*d.* per unit, with a sliding scale reduction down to 4*d.* per unit for lighting, and 4*d.* and 3*d.* per unit for motive power, have been in force.

ELECTRICITY will be the only motive power employed by the Orleans Railway Company on the extension of its line through Paris to the Quai d'Orsay; that is, if the project is approved of by the Minister of Public Works. Electric locomotives will take the trains to the outskirts of the city, where they will be replaced by the ordinary engines, and in this way the long tunnels of the new line will be kept free from smoke. Should the experiment be successful, the Orleans Railway Company will extend the use of electricity to other sections of its system.

TRADE NOTES.

THE Penygroes County School, Carnarvonshire, is being warmed and ventilated by means of Shorland's patent Manchester grates.

MESSRS. MARION & CO., of Soho Square, who enjoy a wide reputation for their photographic appliances and materials, have sent us their new price lists and samples of ferro-prussiate papers and linen, which afford an excellent and infallible means of obtaining accurate copies of drawings, plans, &c., by the simple process of exposure to light and afterwards washing in water. Among other materials supplied by the firm are their cyanographic paper for reproducing tracings, &c., the melagraphic paper for reproducing tracings, &c., in black lines on white ground by exposure to light and simply washing in water, and their gallate-de-fer paper for reproducing tracings, &c., in black lines on white ground by exposure to light and development in one bath only, while their new and improved tracing papers and cloth are specially suitable for ferro-prussiate and other heliographic printing. They are of uniform excellent quality and moderate price.

WE were greatly interested in the demonstration given on Wednesday last by the directors of the London Portland Cement Company, at their works at Northfleet, as to the highly satisfactory fire-resisting qualities of their new building material "Scagliol." Exigencies of space prevent our giving a full account this week, but we propose to do so in our next issue.

BUILDING AND BUILDERS.

THE foundation-stone was laid on Saturday of day schools that are to be built in connection with St. Joseph's Catholic church, Sale, at a cost of over 2,000*l.*

LORD STRATHCONA laid on Saturday the foundation-stone of the Presbyterian church of St. Peter, Beechcroft Road, Upper Tooting, in the presence of a large gathering.

A NEW Welsh Calvinistic Methodist chapel is about to be erected at Carmel, near Holywell, at a cost of 1,000*l.*, which is to supersede a building that dates from 1814.

AN interlocutor has been issued granting warrant for the erection of the new hotel above Princes Street station, Edinburgh.

THE foundation-stone of the St. Barnabas Church, Morecambe, was laid on Friday last. The estimated cost is close upon 7,000*l.* Seating accommodation is to be provided for 700 persons.

LORD GREY (the administrator of Mashonaland) has laid the foundation-stone of a cottage accident hospital at Bishop Auckland. The building is intended to meet the wants of the mining community.

AT Dudley, on Wednesday, the Earl of Dudley laid the foundation-stone of a new grammar school which is being erected from the designs of Messrs. Woodhouse & Willoughby, of Manchester, at an estimated cost of 10,000*l.* The new buildings will accommodate 150 boys, and will comprise a large central hall, five classrooms and head-master's house.

VOLUME LIX. OF THE ARCHITECT Handsomely bound in Cloth, Gilt Lettered
Price 12s. 6d.
Office: 175 Strand, London, W.C.

THE Guardians of St. Olave's, Borough, have voted 2,000*l.* for the erection of a Roman Catholic church and a Protestant church in connection with their new workhouse now in course of building at Ladywell, Lewisham, which is to accommodate 600 inmates.

THE foundation-stone of a new smallpox hospital for Barnsley and the townships round about was laid last week at Lund Lane, Monk Bretton. The hospital, which is in course of erection by the Barnsley Corporation at a cost of 6,000*l.* on a site purchased from Colonel Wombwell's trustees for 1,000*l.*, will be built in five blocks, and will provide accommodation for sixteen patients.

THE foundation-stone of the new cottage homes which the Aston Board of Guardians are erecting at Gravelly Hill were laid on Tuesday. The architects' plans for these homes were originally drawn for the accommodation of "families" of thirty, but at the instance of the Local Government Board they have been amended, so as to provide for "families" of not more than sixteen, space being found in the altered designs for a total of 250 children. The new buildings are divided by a broad roadway into two sections, one for girls and one for boys. In the centre of the former is situated the superintendent's house; at one end is a probationary lodge for the detention and examination of new-comers, and at the opposite extremity are the church and schools and the infirmary. In each section are seven homes for the accommodation of sixteen children each, and one for twelve children. The boys' department contains workshops, in which they will be taught tailoring, shoemaking, carpentry and fitting, and a large swimming-bath is also provided. The contract, which amounts to 42,000*l.*, has been let to Messrs. W. Lee & Son, of Aston.

VARIETIES.

SPECIAL services were held at St. Cyprian's Church, Edge Lane, Liverpool, on Sunday, on the occasion of the reopening of the building, which has been renovated and improved.

THE spacious castle which the Duke of Fife has been building on his Braemar estate is rapidly approaching completion, and will be ready for occupation within the next few weeks.

A NEW police-court for the Highgate district, at the corner of Archway and Bishop's Roads, near the railway station, was formally opened on the 20th inst. The new building, of which the foundation-stone was laid on August 5 last year, was erected by the Middlesex County Council at a cost of about 6,000*l.*

THE new hospital at Aldershot for the wives and children of soldiers has been opened by the Duchess of Connaught. It adjoins the Cambridge Hospital, and the foundation-stone was laid by the Duchess a year ago. It is a commodious, well-arranged building, and contains all the latest improvements and the best-known appliances for the nursing of the sick. The Duke of Connaught accompanied the Duchess.

MR. T. W. CUBBON, who is architect of the Wells Lane Schools, Birkenhead, has recently received instructions from the Clothworkers' Company to proceed with an important educational scheme in the Isle of Man, comprising the erection of a new higher grade school, also a new science and technical school. It has also been decided to materially enlarge two of the existing schools. Mr. Cubbon has just completed a new pupil teachers' centre and science school for the Douglas School Board, which is the fourth he has carried out for this Board.

EDMUND HAROLD CAMPIN, the youngest son of one of our contributors, has won the silver medal for proficiency in mathematics at Aske's Hatcham School this year. He has also taken second-class honours in the Senior Cambridge Local Examination. In the open competition for London County Council Intermediate Scholarships he gained the eighth place, June 1897. He has also taken the form prize for the year.

THE new science laboratory or technical department of Bromsgrove School has been completed, and the celebration of founders' day was selected as a suitable occasion on which to perform the opening ceremony. The laboratory stands at the corner of the prettily laid-out quadrangle formed by the present building of the school. It is designed in the English Renaissance style of the early part of the seventeenth century, and is built of sand-faced bricks and with Monk's Park stone, and a covering of purple-red Broseley tiles. The building, which is of two storeys, comprises a lecture-room, chemical and physics laboratories, a dark room for photography, carpenters and turners' shops and stores. The work has been carried out by Messrs. J. & A. Brazier, of Bromsgrove, from the designs and under the superintendence of Messrs. Lewis Sheppard & Son, of Worcester, and at a cost of something under 1,000*l.*

SHERINGHAM, like many another rising seaside resort, has grown ashamed of the rustic and primitive beauty which has hitherto constituted its charm, and is now eager to obliterate its natural characteristics and put on the commonplace appearance which renders one place of the kind practically indistinguishable from another. To this end an esplanade has been constructed and a gorgeous new hotel erected, both of which were a day or two since inaugurated with all the pomp and circumstance to be derived from brass bands and a profusion of bunting.

IN submitting the accounts for the first half-year, showing a net profit of £5,409, the directors of the Royal Aquarium Society state that the seven years' refreshment contract held by the present contractors will expire on September 14, and a contract under new auspices and more favourable to the Society has been entered into. A transfer of the Society's mortgage is being negotiated at $3\frac{1}{4}$ per cent. in lieu of $3\frac{3}{4}$. The art metal exhibition necessitated heavy expenditure and precluded large profits. The expenses were, however, more than covered, and the directors report that, without exception, every week's business has resulted in profit to the Society.

A NEW theatre was opened at Dalston on Monday evening. The building is not strictly a new one, being, in fact, a conversion of a circus which was known as the Colosseum. The auditorium consists of pit and stalls, with an amphitheatre rising from a spacious dress circle to the gallery. The decorations, in pale green, white and gold, with crimson upholstery, are bright, and the proscenium is flanked by two large stage boxes and there are a dozen smaller boxes under the circle line. The lessees are Messrs. Edward Compton and Milton Bode, and the theatre will be run on the weekly change principle.

WORK in connection with the demolition of the tall chimney stalk at the New Street Gasworks, Edinburgh, is now in hand, and the consequent removal of an eyesore from the Princes Street valley will therefore shortly be effected. The chimney was built in the year 1845, and was designed by Mr. Mark Taylor, engineer to the company. Mr. George Buchanan, civil engineer, and Professor Gordon, both of Glasgow, were also consulted. The stonework was built by Mr. James Gowans, Edinburgh, and the brickwork by Mr. James Bow, of Pollokshields, near Glasgow. The total height of the chimney is 329 feet from the ground line. The stone pedestal is 30 feet square and 66 feet high. The brick shaft is circular, 26 feet 3 inches diameter at the bottom, tapering to 15 feet diameter at the top, and the inner barrel is $22\frac{1}{2}$ feet diameter at the bottom tapering to 12 feet diameter at the top. There are few chimneys even at the present day higher than the one that is about to be removed from Edinburgh, and at the time of its erection it was considered one of a few of such dimensions. Every precaution has been taken by the commissioners to insure the safe removal of such a huge structure without mishap, and the contractor, Mr. W. J. Furse, of Nottingham, is setting about it in a workmanlike manner. The refuse material is to be utilised in the concrete for the building of the new gasworks at Granton.

THE new police-station for Lichfield, which has been erected by the standing joint committee of the Staffordshire County Council, is now complete, and will be occupied in the course of a few weeks. The principal entrance is in Wade Street, and the appearance of the buildings at once shows that great care has been taken to make the style harmonise with the general character of the city. The buildings are faced with sanded Leicester bricks with Hollington stone dressings, and are set back from the street with iron railings in front. The public entrance is in the centre, with superintendent's office and charge-room on either side. At the side of the charge-room is the tramp office, having a door from the charge-room, but having a separate external entrance. Immediately opposite the door at the back of the charge-room is the cell corridor, having four cells of regulation size opening from it, with lavatory, &c., in the centre. The cell windows overlook the prisoners' yard, which, being covered with an iron grille, renders it impossible for outsiders to communicate with the prisoners. The entrance to the constables' quarters is at the left-hand side of the Wade Street front, and gives approach to a square hall with staircase leading to the living rooms. At the back of this hall is the cleaning-room and the boot-room. On the first floor are the constables' quarters, consisting of a recreation-room, a kitchen, with pantry adjoining, containing separate locker for each man, a dormitory for six men, a sick room, a large bath-room, lavatory, scullery, &c. The superintendent's house fronts Frog Lane, and the entrance to the parade yard is also in Frog Lane. The cells are heated and ventilated in a special manner. Under the cell corridor are provided hot and cold-air chambers, with external gratings to supply the cold chamber with fresh air, which will enter the hot-air chamber near the bottom and so pass between the hot-water pipes and rise from the top of the hot-air chamber through flues into the cells. The foul air will be extracted from the cells by means of flues carried into a main flue

which is specially heated to create a draught. The whole of the interior has been designed with simple and yet pleasing detail. The principal entrance has a dado of glazed tiles, and the chimney-pieces, &c., of all the principal rooms are of glazed faïence, while the walls and ceiling of the cells are of glazed bricks, thus entailing a minimum of work in cleaning. The floors of all the principal rooms on the ground and first floors are of wood blocks. The cost of the whole has been about 5,500*l.*, and it has been erected from the designs and under the superintendence of Mr. John P. Osborne, F.R.I.B.A., of 95 Colmore Row, Birmingham, the contractor being Mr. John Gethin, of Shrewsbury, and the clerk of works, Mr. W. Sier.

BUILDERS' BENEVOLENT INSTITUTION.

THE fifty-first annual meeting of the Builders' Benevolent Institution was held on Thursday, July 21, at the offices, 35 Southampton Row, Bloomsbury, W.C. Mr. Charles Wall (president) occupied the chair, supported by Messrs. Thomas Stirling, H. Holloway, E. V. New and other friends of the Institution.

Major R. A. Brutton (secretary) read the annual report, which stated that the committee desired to express to the subscribers their thanks for the continued support to the charity. Last year being the Queen's Jubilee, and also the Jubilee year of the Institution, every eligible candidate was rejoiced by receiving the benefits of the charity. This was very satisfactory, and it was hoped that the increased liability of expense would be cheerfully met by subscribers. By the lapse of time, the decease of many liberal contributors and other causes, new subscribers were urgently needed, or the Institution might eventually have to be curtailed in the dispensation of the great good it was so happily the means of affording. The warmest thanks were due to the president, Mr. Charles Wall, for the interest he had taken in the welfare of the Institution. During the past year there had been four deaths amongst the pensioners, and three pensioners had been elected. The annual dinner will be held at Carpenters' Hall on Thursday, November 17, when Mr. Benjamin J. Greenwood, of the firm of Messrs. Holliday & Greenwood, would occupy the chair.

The Chairman proposed the adoption of the report and accounts, which was seconded by Mr. New, and unanimously agreed to.

On the motion of Mr. Thos. Stirling a cordial vote of thanks was passed to the retiring president, Mr. Charles Wall.

Thanks were also accorded to the vice-presidents and to the hon. treasurer (Mr. George Plucknett, J.P.), with a request that he should continue his valuable services.

A similar compliment was paid to the committee, the retiring members being reappointed with the addition of Mr. A. Ritchie.

The hon. auditors were re-elected, and a vote of thanks accorded them for their services.

The Chairman proposed that Mr. Benjamin J. Greenwood be the president for the ensuing year, and believed he would do his utmost for the charity.

Mr. New seconded the motion, which was agreed to.

On the motion of Mr. Holloway, a cordial vote of thanks was passed to the chairman for presiding, and the proceedings terminated.

MUNICIPAL TRADING IN ELECTRIC POWER.

IN a letter to the editor of the *Times* Sir Frederick Bramwell, C.E., writes :—

In 1882, sixteen years ago, you did me the honour to insert a letter having for its title "Something more than the Electric Lighting Bill," in which I called attention to the onerous conditions which by the Electric Lighting Act of that year it was sought to impose upon all private enterprises for the purposes of supplying electric energy.

In this letter I pointed out how peculiarly unreasonable it was that a then new industry should be stifled at its birth by the imposition of provisions in favour of municipalities which had never been applied to its immediate competitors the gas companies, or even to railways, &c.—provisions which allowed municipalities or other governing bodies of any district where it was proposed to inaugurate an electric lighting company to acquire at the end of fifteen years the electric undertaking on the mere value of the materials suitable for the work at the time of purchase.

If the municipality did not happen to buy, its chance of purchase was not gone for ever, for at the end of a further five years the option re-arose, and so on from five years to five years.

Thus, as I pointed out, "as long as there is no profit or a poor profit, you, the undertakers, may continue to work, but the instant you get anything like an adequate return, then we will come and buy you up at a price which must inevitably be a comparatively small fraction of the capital you have laid out in your undertaking."

The Act which was passed varied the Bill in extending the fifteen years to twenty-one years, and the five years' "recurrence of option" to seven years.

As was to have been expected under such provisions as these, no private capitalists would risk their money and go to work, and for six years England lagged behind all the other nations in this industry.

This had become so obvious that in 1888 an Act was passed extending the twenty-one years to forty-two years. But the vicious principle of municipal trading still prevailed in that Act, and at the end of forty-two years the undertaking was to be acquired upon the then value of the mere materials.

This year there has been a joint committee of the Houses of Lords and Commons on electric energy (generating stations and supply), the report of which committee has just been published.

From that report it will be seen that, as regards undertakings supplying energy in bulk at high voltage, to be used not only for the purpose of electric lighting, but of power, the committee think the provisions of the Electric Lighting Acts enabling the local authority to purchase after a term of years inapplicable as a general rule—that is to say, the committee realise that the conditions imposed by the Act of 1882, whereby the interests of the municipalities were fostered at the expense of private enterprise, were inconsistent with the free development of this great industry, and they further realise that the modifications of the 1888 Act are not by any means sufficient or satisfactory, and the evidence before the committee showed that England is still behind other countries in its commercial employment of electric energy.

Since the issue of this report of the joint select committee there has passed through the House of Lords a Bill promoted by certain influential coal and iron masters in the Midlands (Nottinghamshire, &c.), which Bill is entitled a "General Power Distributing Bill"; this has for its object the supply of electrical energy for lighting, power and every other purpose for which it is applicable over an area of some 2,000 square miles, being the area of a circle of 26 miles radius, with its centre at Warsop, in the colliery district of Nottinghamshire, where the generating station would be placed.

This lords' committee passed the Bill and its clauses unanimously. There is no purchase clause in the Bill at all. It has now to be considered by the House of Commons. It has been read a first time, and the second reading is likely to take place on Friday, or on some other very early date.

The sole opponents are certain municipalities. These are using every effort to obtain the rejection of the Bill on the second reading, or, failing this, they seek that an "instruction" should be given to the committee that would be appointed to consider the Bill.

That is to say they invite the House of Commons to reject a Bill which is the outcome of the principles approved by the joint committee, embracing certain of its own members, without hearing (through its committee) any evidence at all; or, failing that, they ask that the judgment of the committee which would hear the evidence shall be fettered by the "instruction" of the House that has not heard the evidence.

In short, by every means in their power they hope to render the report of the joint committee a dead letter, and to continue to uphold the mischievous system of municipal trading.

FIREPROOF CONSTRUCTION IN AMERICA.

(*Concluded from last week.*)

Third, Constructions with Light Metal Constituents.—Fireproofing material in the form of a flat arch or flat slab acts like a beam—the upper portion of the section being in compression and the lower portion in tension. As none of the materials are as strong in tension as in compression, light metal elements are introduced to strengthen the portion of the section that is in tension. In this manner a much thinner and lighter construction of the requisite strength may be obtained. In assembled constructions the metal elements are embedded in the mortar of the joints; in monolithic constructions the metal is embedded in the material while in a plastic state. The metal generally consists of steel or iron in the form of wire, rods, bars or sheet metal expanded in open meshes. If properly embedded the metal adds greatly to the strength of the construction. As that portion of the material which is in tension is usually the under side of the construction, the metal, in order to develop its maximum efficiency, should be located as far as possible from the neutral axis, or near the under surface of the construction. In this position, however, it is very much exposed, and in case of a fire of any magnitude the heat would soon render the metal constituents valueless as an element of strength. In construction of this class the embedded metal should, therefore

be located as far as practicable from the under surface. A building constructed entirely of incombustible materials is not necessarily fireproof. If the building contains steel or iron-work, and is not suitably protected, the heat from a very insignificant conflagration caused by the combustion of the furniture or other contents may so seriously affect the strength of important iron members as to cause the complete wreck of the structure. It is, therefore, highly essential that the structural iron be thoroughly protected. This is accomplished ordinarily by—first, materials of construction, and, second, materials of finish.

In the former case, the same materials as are used for the walls and floors are built around the columns, girders and beams, so as to completely encase them, the thickness of the cover varying from 1½ to 4 inches, depending upon the character of the building and the degree of fireproof efficiency required. The monolithic constructions forming a solid continuous protection around the columns, or, in case of girders and beams, forming an integral part of the floor construction between the beams, are vastly more tenacious and efficient than any other. Protective coverings, consisting of assembled parts, even though bound together with wire or band iron, are liable to crack at the mortar joints and fall during a hot fire or when suddenly cooled by a fire stream.

When materials of finish form the protective covering they usually consist of plaster, cement, a veneering of natural or artificial stone, of sheet metal or of a combination of these. Cement or plaster on wire lath is superior to the other materials of finish named for protective purposes. Suitable furring should in all cases be provided, so that an air space will intervene and prevent the plaster from coming into contact with the iron member. This will prevent any fluxing of the iron under high temperatures and will permit the transmission of heat only by radiation—a much slower process than by direct contact. When designed so as to form two or more thicknesses of wire lath and plaster with air spaces intervening, the efficiency of the protection is largely increased. The usual practice of incasing the columns and girders with a single thickness (generally 1 inch or less) of plaster and wire lath is entirely inadequate in most cases and is only admissible in buildings containing insignificant quantities of combustible finish and contents. The columns and girders being the essential members of the steel skeleton frame, they should in all cases be thoroughly protected.

The protection which any given method or system of fireproofing provides for the structural iron depends not only upon the character and thickness of the actual covering, but also upon the distribution of the material of construction. When, as for example, in the segmental arch form, the floor material is aggregated or massed about the beams and girders, a large percentage of the total material is in the immediate vicinity of the steel beams. On the other hand, if the material is more uniformly distributed, as in the flat slab form, a less percentage of the total material will be found near the beam. It will be evident that a higher degree of heat or a longer application of it will be necessary to raise the larger mass of material to a certain temperature than will be required to raise the smaller one to the same temperature. The beam being within the protecting material, it follows that it will be more effectually protected by the larger mass of the material.

Types of fireproof flooring in which the under surface of the materials of construction is below the lower flange of the steel beams, afford generally a better protection for the beams than those types in which the beams project below the flooring and are protected by a covering. In the latter case three sides of the girder or beam covering are exposed to the flame and heat in case of fire. The thickness of the covering in such forms of construction should be carefully designed so as to provide suitable protection, as the special conditions may require.

The question as to whether iron and steel will oxidise or rust when in contact with materials of construction is one of vital importance. Cement mortar and the ordinary stone concretes made with it have well-known preservative qualities. In basement floors or other locations where more or less moisture may be present, care should be taken that the concrete in contact with the iron be a "full" concrete; that is, a mixture in which the cementing material completely fills the voids and is in contact with the entire surface of the iron. "Cinder" concrete is a comparatively new material. Its effect on steel and iron has been carefully and very thoroughly investigated during the past two years. It has been shown that under normal conditions cinder concrete is entirely harmless in this respect. The plaster-of-Paris compositions have been used for many years in France and other parts of Europe without causing any injurious effects whatever when in contact with iron or steel. New materials, and especially such as are produced by secret or patented processes, should be thoroughly tested and proved to be absolutely harmless before accepting them as suitable materials for building construction.

Economy in fireproof construction can be secured only by a

scientific treatment of the subject. The actual and relative expansion of the materials due to heat and the deflections caused by unequal heating must receive careful consideration. Some of the properties of structural steel when heated are as follows :—

At about 575 deg. Fahr. 10 per cent. of the strength is lost.

At about 750 deg. to 800 deg. Fahr. 50 per cent. of its strength is lost.

At about 1,000 deg. to 1,200 deg. Fahr. 75 per cent. of its strength is lost.

The limit of safety is in some cases dependent upon temperature and in other cases upon expansion. The protection of the steel skeleton frame should in all cases be ample to prevent temperatures approximating to the safe limits.

In designing the fireproofing of a building it is important to know the character of the interior finish and the purposes for which the building is to be used, in order that an intelligent idea may be formed as to the intensity and duration of a possible fire. When these details are known a suitable form of construction can be selected, and the protection of the steel skeleton frame designed with accuracy and economy to meet the requirements.

A few hints as to the special adaptations of some of the forms of construction, suitable spacing of iron beams, &c., follow :—

For warehouses, factories, stores, depôts, &c., which may be filled with inflammable and other goods and in which the floors are subject to heavy moving of jarring loads, the segmental arch form of construction will generally be found to be the strongest, safest and most economical. The whole section of the arch being in compression, it can be depended on to retain its full strength and fulfil every requirement of a floor in the most intense and long-continued conflagrations. For similar buildings in which strength is of prime importance and fireproof qualities are a secondary consideration, the forms of construction with light metal constituents will give excellent results and prove more economical than the segmental arch.

For public buildings, libraries and other high-class buildings in which expensive floor finish and highly ornamental plaster effects are desired, the monolithic constructions (preferably the segmental arch form), with flat ceilings of wire or expanded metal give the best results. The monolithic construction will preserve the integrity of the floor finish, and the wire ceilings, if properly constructed, will prevent the cracking and discolouration of the plaster-work.

For office buildings, educational institutions, hospitals, theatres, hotels, apartment houses, residences, &c., in which the combustible contents are limited to interior finish and furniture, the monolithic constructions with light metal constituents and flat wire ceilings are the most economical and fulfil every requirement. The air spaces between the flooring and ceiling in these forms of construction provide a convenient conduit for piping, speaking tubes, electric wiring, &c.

Fireproof floors should be at least 3 inches in thickness. If thinner most of the materials are liable to crack when highly heated and suddenly cooled with a fire stream.

In designing iron-work for fireproof floors the beams should generally be spaced from 5 to 8 feet centre to centre. In wider spacing the construction between the beams weakens rapidly, and excessive thrusts and strains generally result, which should be avoided in fireproof construction. In closer spacing of the beams the ironwork is rarely as economical and the smaller beams are more readily affected by heat.

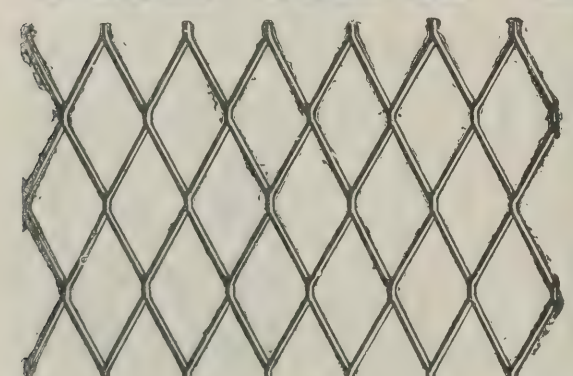
PATENTS.

[*This List of Patents is compiled specially for this Journal by Mr. G. H. Rayner, of the firm of Rayner & Co., Consulting Patent Agents, 37 Chancery Lane, London, W.C., from whom all particulars and information relating to Patents may be had gratuitously.*]

Applications for Patents.

15250. John Hill, for "Improvements in ventilators."

15617. George Elliott and John Thomas Hickson, for "A new or improved process for drying bricks."



15623. Charles Kempshall, for "Improvements in tile-making and punching tables."

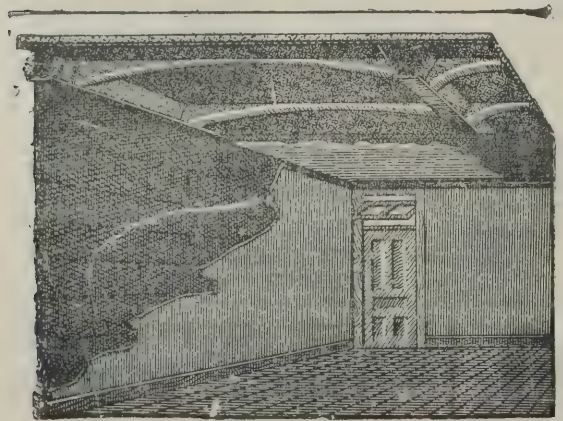
15632. Louis Pollastrini and August Sicard, for "Improvements in or connected with plaster ceilings."

21146. Pearce, for "Vitreous decoration of walls, panels and other surfaces."

To Inventors.—Patents for Inventions, Trade-marks and Designs secured; every assistance given to inventors. Specialists in Building matters. Information free.—Messrs. Rayner & Co., Patent Agents, 37 Chancery Lane, London, W.C.

THE NEW EXPANDED METAL

Meshes from $\frac{1}{8}$th in. to 6 in. wide. Strands from 24 B.W.G to $\frac{3}{16}$th in. thickness of steel.



FOR BUILDING CONSTRUCTION, as supplied to a large number of importa Buildings, both Public and Private, in this country and abroad.

FOR SOLID PLASTER PARTITIONS, 2 inches thick, with Expanded Met Lathing. Fireproof, vermin-proof and practically sound-proof.

FOR FIREPROOF LATHING, for attaching to wooden joists and studs, for wa and ceilings, also for suspended ceilings, ornamental mouldings, encasing columns, girders, &c.— cracking or falling away of plaster to be feared.

FOR CONCRETE FLOORS WITH EXPANDED METAL.—The remarkable resu and advantages of these will be better understood by perusal of the Report hereinafter referred to

FOR EXTERIOR WALLS OF BUILDINGS.—Cement applied to Expanded Met Is not liable to crack or fall away through changes of temperature.

FOR FENCING, TREE GUARDS, WINDOW GUARDS, as supplied to the Roy Parks, leading Railway Companies and landed Estates throughout the Kingdom.

ORNAMENTAL. STRONG. CHEAP.

OTHER USES FOR EXPANDED METAL.—These are innumerable. It can used wherever lattice-work is required, from a letter-rack to a lift-shaft, for garden bordering archways. Is highly ornamental and exceedingly durable, having no joints to rust away.

Being expanded by rapid machinery it is considerably cheaper, strength for strength, than other description of metal lattice-work.

BRASS, ALUMINIUM, or any other ductile metal can be expanded, and the eff is very pleasing, and here again the absence of joints gives great durability to the metal, and rapidity of manufacture allows of very low prices.

CATALOGUES AND PRICE LISTS can be obtained on application. Also copy a REPORT by an EMINENT FIRM of ENGINEERS on the use of EXPANDED MET IN CONCRETE.

The Architect.

THE WEEK.

We have several times referred to the old building in Kilmallock which is known as "King John's Castle." For some years the lower part has been used as a forge. The castle is also an obstacle to a road improvement, and the local authorities proposed to demolish it. The rights of occupancy and of a Board of Guardians are not to be set aside with impunity, and it was therefore difficult to utilise the Ancient Monuments Act for the preservation of the castle. Acting on the advice of Sir Thomas Deane, the Irish Commissioners of Works have, in spite of legal difficulties, secured the loose masonry, and the ruin is therefore in a state of substantial repair. But the smith's forge remains. The Commissioners have been in correspondence with the owner of the castle on the subject of getting clear possession, which they have themselves no power to obtain. A local committee lately proposed to provide a forge for the smith if the Commissioners would make two large arches in the tower, so as to form a roadway through it. The Commissioners are advised that this work would endanger the stability of the structure. The Commissioners, however, have been advised to remove the stone divisions of the two existing arches, to concrete the floor under them, to build a concrete wall in the interior, shutting off the arches from the rest of the castle, so as to prevent objectionable use being made of the structure, to place a door in this wall opening from the side of the arched passage, to concrete the upper portion of the stone vaulting, and to provide for carrying away the water. They have written to the Board of Guardians, who have communicated with them officially, offering to execute these works if and as soon as it becomes possible to do so, by removal of the forge.

The decision of the Court of Appeal in Pethicks' case has much importance for builders who have large contracts in country districts. Messrs. Pethick were the builders of the Dorset County Lunatic Asylum, which cost 52,000*l.* By the conditions they were bound to keep the visiting committee harmless from all claims for damage to main roads by extraordinary traffic. They entered into a subcontract with John Trenchard to provide carts and horses, men to unload railway trucks, and to convey some of the materials along certain roads. No cart or traction engine was to be employed without the consent of Messrs. Pethick. Further, he agreed to indemnify them against claims for damage to main roads. The County Council of Dorset sent in a claim for 231*l.* on account of the extraordinary traffic, and summoned Messrs. Pethick, who were ordered to pay by the justices. The Divisional Court set that order aside. The question was, were Messrs. Pethick responsible after their arrangement with Trenchard? Lord Justice Smith held that the decision given last year in Kent County Council *v.* Lord Gerard was binding, and that the person who was liable was not the person by whom or at whose instance the extraordinary traffic was conducted, but the person by whose order it was conducted. There was no doubt that it had been conducted by the order of Trenchard, and that he might have been made liable. But it was argued that even if that were so Pethicks had ordered it to be conducted. There was no other order than the written contract between Pethicks and Trenchard. It was said that power was reserved to Pethicks under the contract to say what carts should be used. He was not satisfied that that was the meaning of the contract. Reliance was also laid on the clause providing that no cart or engine should be used which Pethicks might think improper for the service. In his opinion those words referred to the fitness of any cart or engine for the work, and did not refer to the contingency of the roads being cut up. On the ground that no order had been shown to have been given within the meaning of the section, he thought that the judgment of the Divisional Court must be affirmed. Lord Justice Rigby said he was of the same opinion. It was necessary for the county authority to show that the extraordinary traffic had been conducted by the order of Pethicks. Lord Justice Vaughan Williams agreed, but he desired to base his judgment on this—that the case did not state sufficient to fix Pethicks with liability. There was nothing to indicate how much of the damage was caused by excessive weight of particular parcels, or what was the nature of the extraordinary traffic in question. On this ground he thought that Pethicks could not be held to be responsible.

The Guild of Handicraft have purchased from the trustees of the late William Morris the plant and presses of the Kelmscott Press, and have made arrangements with different members of Mr. Morris's staff for permanent employment at Essex House, with a view to their ultimate election into the Guild. It is the hope of the Guild by this means to continue in some measure the tradition of good printing and fine workmanship which William Morris revived. The Kelmscott Press blocks being deposited at the British Museum, and the types not for sale, the books to be issued from the Essex House Press will be in a new type, to be designed by Mr. C. R. Ashbee. As this type will not be ready for some months, one of the best of the eighteenth-century Caslon founts has been purchased, and in this the first two or three books will be produced. Of these, the first issue will be Mr. Ashbee's translation of the treatises of Benvenuto Cellini on "Metal Work and Sculpture," which is now nearly completed. This book, which has never yet been translated into English, and which has entailed several years' work, is intended to serve as a pendant to the work of John Addington Symonds; it will be richly illustrated with reproductions of Cellini's works, arrangements having been made with Messrs. Plon, Nourritt et Cie., in Paris, for the use of the *clichés* to M. Eugène Plon's great work on Cellini. Other books to be issued from the Essex House Press will, it is hoped, be as follows:—Sir Thomas Hoby's translation (Elizabethan) of Baldassare Castiglione's "Courtier," Bunyan's "Pilgrim's Progress," Froissart's "Chronicles," the "Poems of Burns," an "Illustrated Account of the Work of the Guild of Handicraft," the "Monographs on famous London Buildings," to be issued from time to time for the Committee for the Survey of the Memorials of Greater London, and "Womburne Wodehouse, Wolverhampton: the Record of an Ancient House."

It is not uncommon in actions for damages against a railway company on account of an accident to hear a judge declare that travellers are not to consider themselves as parcels and entirely in the hands of officials. A traveller is to exercise his own judgment when it can be of use. But under the Employers' Liability Act the order of a foreman is supposed to remove all necessity for thinking. A man on building works becomes like a soldier in the field, who has no discretion about obedience. The judgment in Reynolds *v.* Holloway, given in the Court of Appeal, is additional evidence of so peculiar a fact. The plaintiff was the widow of a ganger, who might be supposed to know something of the risks of building, and who was told by the foreman to take down a small two-storeyed house. There was a matchboard partition, but whether orders were given that it was to be preserved appeared uncertain. At all events, the ganger began with the partition, and in the course of his operations the roof fell on him and he was killed. In the Greenwich County Court the widow was awarded 120*l.*; Mr. Justice Day and Mr. Justice Lawrance, however, held there was no evidence to go to a jury, and entered judgment for the builder. The case was taken to the Appeal Court. Counsel for the builder argued that there was no evidence of the foreman ordering the partition to be removed, and therefore it could not be said the ganger was obeying orders. The Court considered that a negligent order was given, as the deceased man, being a ganger, was ignorant about the proper way to pull down a house; therefore his death was caused by obedience to the foreman's order. The judgment of the County Court was restored. It is cruel to appear as an opponent of justice in cases of this kind, but it is difficult to resist a belief that the ganger could hardly have been ignorant of his risks. There is too often foolhardiness among the men engaged on demolitions, but it is hard to make an employer pay for an excess which brings him no profit.

THE SCIENCE AND ART DEPARTMENT'S REPORT.

IT would appear as if the beginning of the end has at last been reached at South Kensington. In spite of the conflicts between the practical and the official representatives of science and art, we suppose a new museum is likely to be erected, but it will hardly be controlled by the connoisseurs of the Royal Engineers. A great many objects which were bought at "fancy prices" will have to be removed from the cases and destroyed. It would appear as if something corresponding with "the Queen's Tobacco Pipe" has become a necessity if the present system of enriching the museum is to be continued. In the teaching of art there may be many modifications. The ruins of Abbey Mansions in Westminster are not satisfactory comment on the thoroughness of the teaching of architecture in the Royal College of Art, and much else is to be seen throughout the country which reveals the imperfections of the Government system.

The coming events are indicated in the last report of the Science and Art Department by an expression of satisfaction for continuous prosperity which corresponds in a marvellous way with the statements of commercial establishments which are about to collapse. There was during the year a decrease in the number of science classes from 10,500 to 9,102; but that is explained away by saying it is "no doubt largely due to the absorption of the smaller schools in the larger and better-equipped schools." There is likewise an increase of 3,400 in the number of students over the year preceding, but between the years 1894 and 1895 the increase was about 10,000, and between 1888 and 1889 it was 18,500. Consequently in science there is, according to the official figures, not much ground for official congratulation. The statistics of tests of students in science are also unsatisfactory. In 1897 the number of students examined was 101,526, and of their papers 62,261 were passed; but in 1890, with only 86,318 students, there were 114,245 papers passed, so that progress is not manifest.

But, whatever deduction from the figures is arrived at, the reports of the examiners testify to the blaze of triumph which is inevitable with a moribund system of science teaching. In building construction "the percentage of first-class successes is the highest yet obtained." In geometry "the results are all good, all but one, but one of the questions having been correctly answered; the drawing was throughout neat and careful, with few exceptions." The examiners in geometric science are Irishmen, and the want of precision is therefore excusable. There is a "decided improvement" in geology, "a distinct improvement" in human physiology, "a distinct improvement" in general biology, "a decided improvement" in physiography. At the same time, we can realise from other parts of the reports that the progress somewhat resembles the popular notions of a crab's locomotion. For instance, the examiners in botany say, "The papers sent in were, on the whole, satisfactory. It is, however, a disappointing feature in these examinations that candidates reproduce, year after year, erroneous views on many elementary points." Again it is confessed :—"The impression produced by the answers as a whole is one of unreality in the knowledge of the candidates. They often seem to be familiar with terms and ideas, but not with the facts to which the terms and ideas refer; so that when the actual things come before them they fail to recognise them." We imagine that a corresponding judgment should be passed in the other branches of science, although the phrases "decidedly satisfactory" and "decided improvement" are scattered with a liberality that recalls the testimonials of the patent medicines.

Science teaching which keeps students ignorant of facts and things is an anomaly in the country of Bacon. But the Department, having created a peculiar class of science masters, is bound to keep them employed. The teachers, with all their shortcomings, are now, however, strong enough to make the higher officials succumb. A remarkable instance of the weakness of South Kensington is suggested by a couple of the circulars. In December 1897 one was issued, which stated how "it has come to the notice of the Lords of the Committee of Council on Education that in several of the schools of science recently established the proportion of students who continue their studies into the second and third year is so exceedingly small that the school cannot with any justice be considered as a school of science at all." Instructions were therefore given to the inspectors to report any case where 25 per cent. of first-year students, or more than that percentage of second-year students, leave the school before completing the full course, and it was announced: "It will then be a question whether such school should continue to be recognised as a school of science." They were brave words, but they did not cause much commotion in the schools. Before a month elapsed My Lords humbly declared "they have no desire to press unduly by any hard-and-fast rule of percentage on those schools which may, if time be allowed them, establish themselves as schools of science, when it is clear that there is a *bonâ-fide* effort to make them such." In other words, things were to go on as before, for there was not a word about limiting the time to be allowed. What is more, an easy way of earning science grants in any ordinary science and art school was pointed out, thus demonstrating that the Department is more concerned about the numbers attending classes than about the instruction given there.

The art of the Department's students, we are afraid, was of a humble degree. The examiners show a reluctance to describe it which is enough to explain its true character to the initiated. Of the examples of historic ornament it is said, "The sketching on the whole is good, and in many cases excellent, even when the number of marks gained is but small, owing to few questions being answered." In geometrical drawing "the right constructions were so clumsily and inaccurately executed as to be not only of no real use, but actually misleading." In design "much good work is sent up, but there is still an appreciable number of papers which ought never to be sent up as the work of advanced students." In design (honours) "A large proportion of the papers were very much below the standard of what one would expect in candidates for 'honours,' being often quite elementary or even rudimentary in conception and treatment. There were notable exceptions," &c. Than this see-sawing there cannot be better proof that the examiners were perplexed, and, whatever the consequences, dare not describe the work as having practical value.

In architecture the results of 1897 appear more satisfactory, but it will be seen that what Professor Roger Smith admired was work which was done outside the schools, such as drawing from existing buildings, and the credit for which should not be entirely arrogated by the Department. He says :—

> The general results of the examination are considered satisfactory. In one respect, indeed, they are very much so, for the answers, written and graphic, give clear evidence that the attention of teachers of architecture in schools of art (and of their students) has been during the last session more directed than before to the study of existing buildings and work, as the best method of learning architecture. In no previous year have there been so many indications of this study, though they have been increasing from year to year; but now not only the advanced students but many of the average ones have attempted some drawing or description of existing work, and perhaps owing to this a larger proportion of candidates than usual have acquitted themselves creditably.

In other varieties of art we suppose a similar practice is allowed, and an important question is raised whether work which was not executed under the eyes of an official master can with fairness be submitted in the examinations. If, however, the art schools in 1897-98 are not much of a protection against foreign competition in cases where design is essential, for it is not by warships only British supremacy is to be upheld, there is a likelihood that for a term at least they will become still less of a defence. Mr. Sparkes, to whom any success gained by the schools is mainly owing, has resigned. At Lambeth he not only brought one of the humblest of schools into a state of efficiency which made it a rival of the Academy school, but by his influence he raised the character of some of the local industries. At South Kensington there was a wider sphere for his organising power if departmental jealousies could have remained unexcited. But, like other able teachers, he was hampered, and such success as was obtained was not always announced. This year, we believe, her students have gained 9 out of 29 gold medals, 39 out of 143 silver medals, and 78 out of 350 bronze medals, which,

under the existing conditions, is a fair measure of success. According to rumour, his successor will be transferred from among the clerks. That experiment was tried in the Art Library, and the contentions over the appointments between the enthusiastic scholar, Mr. WEALE, and the upholders of the competency of clerks to undertake all duties has led to the Parliamentary inquiry which has startled the country. In Austria at one time the Capuchins monopolised civil and military as well as religious posts of importance, and every reader of SCHILLER'S "Wallenstein" knows the consequences. In this country the Civil Service clerk takes the place of the monk; he is the universal genius, the practical man. We hope in naval and military affairs he will outstrategise foreigners; but experience has proved that in dealing with the teaching of art and science he has not been a blessing to the country.

LIGHT AND AIR.*

A FOREIGNER who visits London and does not follow the tracks laid down in his guide book, must often wonder when he sees the announcement of ancient lights painted on the walls of houses in districts where improvements are about to be realised. Respect for windows is not necessarily insured in that way, and the lettering may be often taken as no more than an invitation to treat for rights which have little claim to be considered as absolute and indefeasible, but the announcement is an assertion of rights which it is one of the privileges of a London house owner to possess. Elsewhere there are prescribed rules by which interference with light and air are readily arranged, but in London, and in most English towns, the erection of a new building imparts to any windows which may be in its vicinity a value which they were not supposed to possess. To assess the amount it is necessary to invoke the costly and uncertain processes of law.

Whether a more economical and expeditious course is possible or not is a subject over which experts differ. In Scotland, notwithstanding all the love of litigation among the people, such light and air cases as are familiar in London are unknown. On the Continent claims are also more easily arranged. But, as we have said, the conditions of building in the Metropolis are supposed to be too irregular to be reduced to order without the aid of surveyors, lawyers and judges. The peculiarity is suggested by the various treatises on the subject. No two experts would follow the same plan in writing a book on light and air. The Acts on the subject are not numerous. The judges endeavour as far as they can to be guided by precedents, but somehow circumstances must be accepted which at one time appear to have the precision of science, and at other times have the laxity and freedom which, with all respect be it said, attend when common law and common rights become the arbiters.

What is the arrangement of Messrs. HUDSON and INMAN'S book is, therefore, the first question which will arise in the mind of anyone who has been connected with light and air cases on opening the pages. After definitions of easements and other rights, the authors begin by treating of the "Creation of the Easement of Light by Prescription (apart from Statute) or by Lost Grant." It is followed by chapters on the "Creation by Express Grant, by Statute, by Prescription, by Implied Grant, by Acquiescence." There is a chapter on "Extinction of the Easement of Light," on "Tenant and Reversioner," on "Interference with the Easement of Light by Obstruction," on "Abatement of the Obstruction," on "Remedies by Action," on "Proceedings Generally," and on "Air." There is also an appendix containing forms of agreement and the Prescription Act of 1832. Some diagrams of the usual character required in proceedings are given, and are very clearly executed. The printing is in a style which not only facilitates reference, but helps to impress the reader with the difference between judgments or principles and their applications.

Section 3 of the Act 2 and 3 Will. IV. c. 71, commonly called the Prescription Act, may be considered as the Magna Charta of the possessors of windows, and an exposition of it would be a manual of the law on the subject. It enacts that "When the access and use of light to and for any dwelling-house, workshop, or other building, shall have been actually enjoyed therewith for the full period of twenty years without interruption, the right thereto shall be deemed absolute and indefeasible, any local usage or custom to the contrary notwithstanding, unless it shall appear that the same was enjoyed by some consent or agreement expressly made or given for that purpose by deed or writing." It will be observed that the word "window" is not mentioned in the section, nor indeed in the Act; but as a window is considered to be the eye of a building, the majority of proceedings relate to some cause which affects one of those openings. HARRIS *v.* DE PINNA reveals the peculiarity of English law in considering light as a series of beams converging in an opening made for the purpose, or, to make use of judicial phraseology, "a number of pencils of light which come directly, or by reflection, into a window." The plaintiffs owned timber sheds of several floors. The defendant built a warehouse right up to their boundary. But we are told that "the Court of Appeal in an action for an injunction, held that inasmuch as the light was not enjoyed through definite openings, the easement could not be acquired." Air was of much importance to the plaintiffs as an agent in drying their goods, and probably light was effectual for that purpose also. But law has its fetiches, and the window is one of them. The plaintiffs could, no doubt, have gained their easement if they put up cast-iron framing without any glass, which bore some resemblance to a window, and allowed the admission of pencils of light.

In a scientific sense light is found to have other qualities which are valuable, besides those which enable us to read print of small size, to discern small objects, to perceive differences of colour, and so on, but the law looks on natural light as something provided by nature, and for which, if lost, expensive artificial light has to be provided. If, for example, the owner of an opposite house were to paint his walls of some glaring colour to such an extent as make his neighbour's water-colour drawings, or his carpets, curtains, hangings, and the frocks of his wife and daughters appear unpleasing, it is doubtful whether the sufferer would be able to obtain compensation. A case of the kind was lately brought before the French courts, the sufferer being a ribbon and silk merchant, who found his business was declining because the materials he offered for sale lost the delicate tones which gave them value. The judges sympathised with him, but could not aid him. In England, where we are less particular about chromatical defects, the courts would not be likely to consider a similar case from the artist's point of view. They are obliged to be almost as indifferent to the sanitary importance of light and air, and on that account it would be often advantageous if some modification of the law took place.

Some years ago there was, we remember, a case in Vice-Chancellor MALINS'S Court, which was conducted in a way that might be said to exhibit procedure in a nutshell. The plaintiff was a coffee-house keeper in a court or lane off Holborn. A big building was erected on the opposite side, which he said darkened his premises. Counsel took the narrowest possible basis of attack. Plaintiff's customers, it was said, could not read the papers he supplied as easily as before, and went elsewhere for literary recreation. That point was kept well before the Court by counsel in examining the witnesses. The irascible judge, who set little value on the evidence of experts, and was irritated at the sight of a diagram, went across to the shop. He found a difficulty in reading the first paper he took up, and it is needless to say the plaintiff succeeded beyond his anticipations. It is not always easy to make out so definite an obstruction; but when it can be done the plaintiff is sure to gain. In the coffee-house case there was undoubtedly an interference with the access of air, and in such stuffy premises that was a consideration of at least equal importance with the diminution of light; but counsel prudently avoided the subject, for he knew too well that if sanitary considerations were of any value the court in which he practised should not be allowed to exist. It is difficult to compare the constituents of air at two periods, while it is easy to show by the increase in the gas bills whether light is obstructed. In no class of action is it more desirable to keep to humble realities than in those relating to light and air.

In the coffee-house case the judge assumed that sufficient light to read a penny newspaper was indispensable,

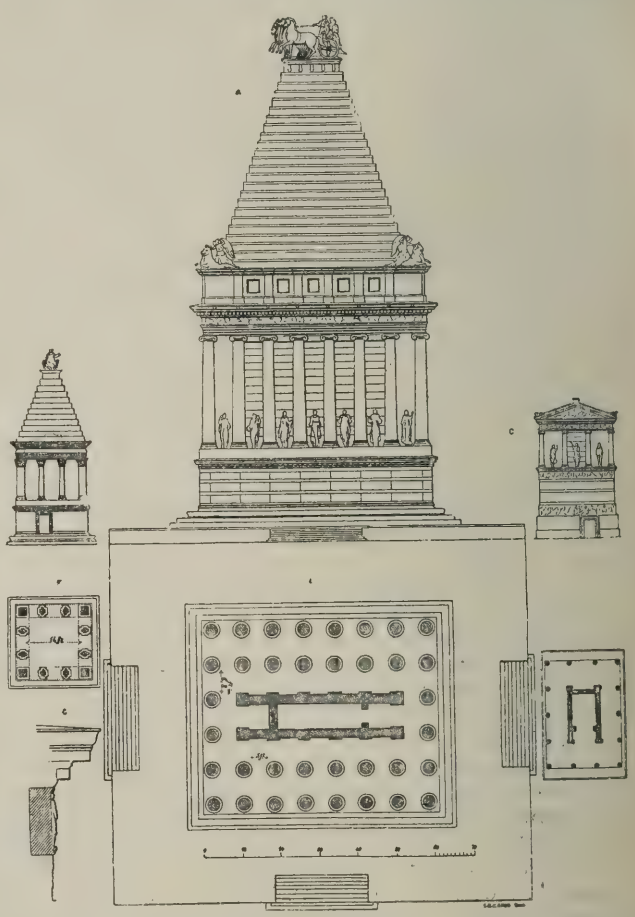
* *The Law of Light and Air*, by Alfred A. Hudson and Arnold Inman, Barristers-at-Law. London: F. P. Wilson.

and therefore existed at a prior time. But cases have arisen where a diminution of light was not considered as penal. One of them, MARTIN *v.* GOBLE, which was tried in 1808, is summarised in the volume before us :—

The plaintiff's house had for twenty years been used as a malthouse. It had lately been converted into a workhouse, and the defendant was obstructing the ancient windows. An action by the plaintiff failed, as the plaintiff did not prove that the light remaining to him was insufficient for the purposes of a malthouse. Sir A. M'Donald directed the jury that it was not enough that the windows were to a certain degree darkened by this wall which the defendant had erected on his own ground. The house was entitled to the degree of light necessary for a malthouse, not for a dwelling-house. The converting it from the one into the other could not affect the rights of the adjoining ground. No man could, by any act of his, suddenly impose a new restriction upon his neighbour. This house had for twenty years enjoyed light sufficient for a malthouse, and, up to this extent and no farther, the plaintiffs could still require that light should be admitted to it. The question therefore was whether it still remained in the condition of a malthouse, and if a proper degree of light for the purpose of making malt was now prevented from entering it by reason of the wall which the defendant had created. The jury found for the defendant.

If a case of the kind came before the courts in our days there is little doubt that the plaintiff would have succeeded. Light is taken to be measurable, and deprivation of a part of it is generally considered an interference with the property of the possessor. As Messrs. HUDSON & INMAN state there were, about the middle of the century, great changes in the law. "If the plaintiff owns ancient lights which are so obstructed that the comfort of his house—if it is a dwelling-house—is interfered with, or so that his premises—if they are business premises—are rendered less fit for any purpose for which they are likely to be used, he is entitled to protection. Whether he is entitled to absolutely the whole of the light which comes to his windows, or only substantially the whole, is not quite so clear, and must remain in doubt until a superior Court decides." But in order to provide against contingencies it is wise "when a house is leased or purchased by an artist or sculptor, or any person whose occupation requires the greatest possible amount of light, and land adjoining the house remains in the hands of the grantor, care should be taken by those advising the person leasing or purchasing the house that all rights of light necessary for his occupation are assured to him." For that purpose it is most useful to preserve elevations which will serve as evidence of the position and area of the windows at the time when the rights are supposed to commence, or rather assume, the initiatory stage, for an easement needs twenty years to grow.

The advantages which belong to Mr. HUDSON'S comprehensive treatise on the law of building—owing to the author's experience as an architect—are also possessed by the volume on ancient lights. It can be trusted, for there are no pages which suggest the amateur in building. It is clearly arranged, and can be read with a satisfaction which is not produced by all legal treatises.



COCKERELL ON THE MAUSOLEUM.

THE writings of the late Professor Cockerell, R.A., have fallen into undeserved neglect. With the following description of an attempt to restore the Mausoleum at Halicarnassus some of our readers may be unacquainted. It was addressed to the late Sir Charles Newton, of the British Museum.

My dear Sir,—The best answer I can give to the questions you do me the pleasure to address me on the subject of the Mausoleum, will be in the artistic language of the enclosed sketch. I will not enter into a critical discussion on this passage, and on the numerous commentaries that have been written in explanation of it; my business, as an architect, is to adhere as nearly as possible to the received text as the programme of my restoration.

The enclosed drawing exhibits an elevation and plan agreeing with the height, width and entire circuit given by Pliny. Beside it, on the same scale, are the tomb at Mylasa and that at Xanthus, which, according to the analogy of all architectural history, must have resembled the Mausoleum, more or less, in its principal features.

One great advantage which we possess over all former commentators on this subject, is the recent acquisition to our Museum of the marbles from the fortress, of the identity of which with the celebrated sculptures described by Pliny I can entertain no doubt. This frieze establishes a very essential fact, viz. the dimension of the order to which it belongs. The relative proportions of the Greek orders being fixed, we ascertain their entire size by a part, as we should that of a statue by a single member "ex pede Herculem." The frieze being 2 feet 5¼ inches in depth, we obtain an order of 37½ feet,* and, applying this order to the dimensions given of the whole by Pliny, 63 feet in the flanks, on the fronts brevius, we find first, a correspondence with one of Pliny's dimensions, 25 cubits, which is remarkable, and may possibly explain that part of his text; and, secondly, from the adjustment of the diameters and intercolumniations of such an order to the dimensions of the sides and fronts and the number of columns given, viz. 36, we have a structure of great beauty and wonder. By such an arrangement the pyramid is supported in the air, literally as Martial has expressed it,† and reposes on a grove of columns, pervious to the eye, yet offering a full and sufficient means of sustaining the superincumbent weight by supports distributed at intervals of 6 feet or thereabouts over the whole surface of the plan, longitudinally and transversely. That so bold and unusual a mode of sustaining the superstructure may have existed we have evidence in the tomb at Mylasa, which was still more astonishing in this respect, though smaller in dimensions, since the pyramid was sustained on a periphery of twelve columns, the interior space having no support whatever, and offering a void of 14 feet, while in the proposed restoration that

void does not exceed 6 feet.‡ The conditions of taste appear to me to be sufficiently fulfilled by the arrangement I have proposed; we obtain a disposition most approved in Greek architecture, having eight columns in either flank, and six in either front, and six in either flank in the second row,§ making a total of 36.

* The diameter of the columns was probably about 3 feet 4 inches, a respectable dimension, and exceeding by one-half that in the French restorations. I have given the frieze that larger proportion which the Ionic examples of Athens afford, rather than the Asiatic. It may well be presumed that a frieze destined to receive workmanship of so superior a quality might have the utmost extension which the order admitted.

† In the line from the "De Spectaculis"—"Aere nec vacuo pendentia Mausolea."

‡ It is by no means necessary to suppose the superstructure of the pyramid to have been a solid. The pillars may have been elongated as piers above the entablature, so as to carry a pyramid of ashlar construction similar to that of Mylasa.

§ In the language of Greek architects, peripteral, dipteral, pycnostyle in the flanks, and systyle in the fronts.

The next point to notice is the narrow and elongated cella resulting from this plan, a remarkable authority for which has been discovered in the remains of a monument from Xanthus, lately acquired for our Museum by the labours of Sir C. Fellows, the restoration of which shows that a tomb was not disposed as a temple, with a cella ample enough to receive the statue of a god, but simply as a receptacle of the remains of the body, perhaps of a statue, in honour of the deceased.* A consideration which has escaped most of the commentators, except Caylus, is the remarkable phrase of Pliny, "in metæ cacumen se contrahens," most of them having adopted the depressed pyramid after the Egyptian proportion. Now we have the meta constantly expressed in bas-relief and ancient painting, and always in an elongated conical form, a form perfectly adapted to this kind of structure, which was to strike rather by its altitude than its spread, and which, indeed, reposing upon an elevated cubical base of perpendicular sides, would thus present a much more harmonious inclination than that of the Egyptian pyramid. The inequalities of the sides of this parallelogram are also remarkably adapted to the area which the quadriga at the top would occupy.

It would encroach too much on your memoir to explain the details, such as the podium, the order, and the Attic,† with which I have thought myself warranted, by direct authority or analogy with other monuments, to combine with the parts of this building already known to us, the requirement always being that we should produce, from all the evidence at our command, a probable restoration, at once beautiful and marvellous, and according with the universal voice of antiquity. You will see that I side with you in believing that this monument did not cover the whole space circumscribed in 411 feet, which is nearly two-thirds of that occupied by the Parthenon itself; for though the work of affection of a powerful queen, and at the same time a product of personal ambition in the illustrious artists employed, it is not likely that it rivalled the great national and religious monuments of the Greeks in bulk and expense, still less in earnestness of purpose and loftiness of motive. Indeed, a comparison of the elevation of the Mausoleum, with those of the monuments at Mylasa, and at Xanthus, as they are represented, will show that it is disproportionately extensive and magnificent for the class to which it belongs. A professional estimate of the cost rather occasions my surprise at so sumptuous an effort in a country so politically insignificant, and I would here venture the suggestion that Caria, like the smaller kingdoms of Naples, Bavaria, Sardinia, and others, furnishing the revenues and sustaining the office of a king without the national responsibilities which encumber more extensive monarchies, may have indulged, as we have abundantly witnessed in modern examples, a greater magnificence of ornamental works than countries with greater territory and revenue, such as England, France, or Spain.

May it not also be supposed that Artemisia, while she indulged that disposition to Sutteeism which has always been applauded among the Asiatic nations, adopted at the same time a very wise policy in employing her hoarded wealth on a work which would occupy, during many years at least, that large body of artificers whom Mausolus must have assembled at Halicarnassus for the execution of his great works?

The hypothesis of a solid pyramid and cube surrounded by thirty-six columns, and those of a petty proportion, in a single row, is, as you remark, an inartificial and clumsy restoration of what we are told was a wonder of art; and such a structure would never have been made the subject of that dissertation by the renowned artists who reared it, Satyrus and Phiteus, the loss of which we must ever regret. Moreover, the solid mass would probably long have existed as a tower of defence, like Hadrian's Mausoleum, or that of Augustus, and would have left some traces at the present day; for it would not have been built of squared stones, such as might have applied to the building of the subsequent fortress, but would have been of the order of masonry called "emplecton," or rubble, with layers only, and a facing of solid square stone, or possibly bricks, and much of the materials would consequently not be worth carrying away.‡ Pray make such use of this essay as you may please—meanwhile I am rejoiced to offer in your society my tribute of admiration to the perseverance and skill, and true liberality, which have been so successfully exercised in our favour by Sir Stratford Canning at the Sublime Porte. By the acquisition of these marbles, he has added an essential link to that chain of monumental evidence in our museum, out of which may be developed the history of ancient art; while in these, the acknowledged works of some of the most renowned artists of antiquity, we behold one more example of that Greek genius, which will probably be followed with unequal steps by the present and future generations.—I remain,

C. R. Cockerell.

* See the model in the Lycian room at the British Museum. That such an arrangement of the cella as it exhibits may be obtained from the fragments themselves, and the observations made by Mr. Rhode Hawkins, I was enabled to demonstrate to that gentleman when, by his ingenious father's introduction, I had the honour, as a veteran in antiquities of this kind, to be consulted by him.

† The choice of Ionic need hardly be adverted to, since its employment was almost universal in Asia Minor, or, we should say, in Ionia, the country of its invention.

‡ We learn from Vitruvius, ii. 8, that the palace of Mausolus was built of brick, the decorations being of marble.

VIGNOLA.

THE "Legislator of Architecture," Giacomo Barozzi, usually called Vignola, from a place of that name in the Modenese, where he was born in 1507, was son of Clement Barozzi, a Milanese, who, not being suitably provided with the aids of fortune, and apprehending the effects of civil discord, left his abode at Milan for a retirement at Vignola, where he died while this son was yet very young. Thus early deprived of his best support, Barozzi yielded to the direction of genius, and betook himself to the study and practice of painting in Bologna. This pursuit soon discovering to him the necessity of a good knowledge of perspective, he so earnestly laboured to possess himself of that part of science as to supply the want of instruction by the invention of a method for himself. This he has given in a treatise entitled "Le due Regole della Prospettiva Practica di Giacopo Barozzi da Vignola," republished Coi Commentarj di Egnazio Danti, in Roma, 1583, folio. While the exercise of his pencil supplied him with the necessaries of life, what leisure his occupations of that kind left him he employed in investigating the principles of those arts; he could not be content to practise from a sole habit of imitation. It was during this first residence at Bologna that he is said to have furnished Francesco Guicciardini, the celebrated historian (then Governor of that city), with some excellent designs, afterwards executed at Florence in tarsia, a sort of mosaic of differently coloured woods formed into landscapes, architecture and other picturesque representations.

The passage was easy, from a deep acquaintance with geometry, perspective and design, to architecture. He had carefully studied Vitruvius, yet the attention he bestowed on that author served but to convince him that something more than writing could teach was wanted to form the real architect. Where to seek this the custom of all his predecessors in the art had informed him. Arrived in Rome, he endeavoured to maintain himself as before by his pencil, with a success by no means equal to his industry; and therefore, throwing aside the pallet in disgust, he sought a new resource in measuring the ancient remains for the Academy of Architecture, newly set on foot in Rome. This employment, conducive alike to his subsistence and improvement, engaged his attention so strongly as probably to have given birth to the "Treatise on the Five Orders" under his name, which all conversant with this study must have read, and some prefer to whatever else has been written on the subject. He next became assistant in the Belvedere to Giacomo Melinghini, of Ferrara, an excellent architect, and was allowed to frequent the meetings of the Academy of Architecture, where Marcello Cervini, afterwards Pope Marcello II., Maffei (afterwards Cardinal), Alexander Manzuoli, and other persons of distinction attended. They employed Vignola in designs and works that contributed to his support and extended his reputation.

Francesco Primaticcio, a Bolognese and excellent painter, coming to Rome about this time from France to collect pictures and procure copies of the most celebrated statues and reliefs, in order to their being cast in bronze as ornaments for the royal palaces, singled out Vignola for his assistant, and at his return carried him into France, where he passed two years in planning many works which failed of execution, throuhg the distress of the times by the foreign wars and civil disturbances with which Francis I. was continually harassed.

Returned to Bologna, he gave a design for the front of St. Petronio, much approved by Giulio Romano and Christoforo Lombardi, architect of the cathedral at Milan. In the Facciata de' Banchi, that makes a sort of wing to the cathedral of Bologna, his dexterous management of the site and some old buildings that could not be removed exhibited a further most advantageous display of his ability, though his design was dropped short by the omission of two turrets that would have added greatly to its effect. At Minerbio, near Bologna, he built a palace for Count Isolani. But the most important service that neighbourhood owed to Vignola was his conducting the Canale del Naviglio, which ran three miles wide of it, into Bologna; an achievement spoken of with high applause by Vasari. Meanly recompensed for this great work, he removed to Piacenza, where he gave the plan and superintended the foundations of the Ducal Palace, of which he left the further direction to his son Giacinto. The citadel of Piacenza was likewise formed by him. It is not easy to ascertain either the number or the dates of the various edifices of this great artist dispersed through Italy. Some of them are the churches of Mazzano, St. Oreste, della Madonna degli Angeli in Assisi, and a beautiful chapel in that of St. Francesco in Perugia.

Upon his revisiting Rome Julius III. appointed Vignola to be his architect. He was entrusted with the direction of the Acqua di Trevi and the construction of the Villa, without the Porta del Popolo, called Papa Giulio. At a small distance on the Flaminian Way Vignola built a chapel in the style of the ancient temples, called St. Andrea di Ponte Molle, a work much applauded. The plan of it is rectangular, the pilasters Corinthian, without pedestals. In Rome he refitted that Palace of the SS. de' Monti which has since been called the Palace of Florence, being become the property of the Grand Duke. For the same family he began a palace opposite that of the household of Borghese, but was not allowed to conduct it much above the foundations. The Cardinal Alexander Farnese, who thought highly of Vignola's intelligence of his art, committed to him that part of the great Farnese Palace which contains the famous gallery painted by the Carracci. By his order likewise Vignola built the elegant Corinthian portal of St. Lorenzo in Damaso, and a rustic door to the Farnese Gardens, that does credit to its inventor. The great favour of this Cardinal to the Order of Jesuits suggesting to him the building of the magnificent Church del Gesú, Vignola was employed to design and conduct the fabric. The foundation was laid in 1568, but the superstructure was not carried on by him to its termination. So far as it had the benefit of his direction it has every merit; but the alterations made in his plan by Giacomo della Porta, who succeeded him in the superintendence, are by no means to the advantage of the work.

St. Anna de' Palafrenieri, near the Vatican, is supposed to have been built by Giacinto Barozzi, after a design of his father Giacomo—the Oratory of St. Marcello, the Cappella Ricci in Santa Caterina de' Funari, the Deposit of Cardinal Ranuccio Farnese in St. Gio. Laterano, are all believed to be inventions of Vignola.

But if every proof of his skill hitherto specified were away, the palace of Caprarola, about thirty miles from Rome towards Viterbo, would by itself establish the superiority of his professional talents. This singularly magnificent and commodious edifice stands solitary, on the brow of a barren hill, surrounded by other rocky eminences and opening into a delicious country. The offices are distributed into several courts, round the midrise of the hill, on whose summit the palace is placed. It is externally of a pentagonal form, flanked by five bastions in manner to give it the commanding air of a fortress. When the visitor has passed the entrance he finds the area within is circular, and the fabric rises by two storeys of porticoes. One side of the pentagon is occupied by a grand loggia and staircase, and in the other four there are on each storey four great apartments complete, which are kept free from all communication by means of the porticoes that run round the great circular court. More detailed descriptions of this masterpiece of a great master may be seen in Vasari, Danti, and, with designs of the whole and the parts, in D'Aviler's "Cours d'Architecture." It may, however, be useful to add that this palace is also attractive for the paintings of the Zuccari and the perspectives of Vignola that adorn it, as well as for its architecture. Barbaro upon a critical survey of the whole, for which he was eminently qualified, is said to have exclaimed, "Vincit præsentia famam."

After the death of Michel Angelo, Barozzi was declared architect of St. Peter's, and in that office erected the two lateral cupolas. When the Baron Berardino Martirani arrived in Rome from Spain to collect designs for the Escurial, and had got together twenty-two by the most eminent architects of Italy, he showed the whole collection to Vignola, who, judiciously selecting and combining what was most masterly and congruous in the ideas of so many great artists, and adding his own to their best conceptions, composed a design greatly superior to any single one that had been shown him. This, when presented and examined, was favoured with the preference of the monarch and an invitation of its author to superintend its execution, an honour his attachment to Rome would not permit him to accept. In regard to the general esteem of his probity and ability he was commissioned by Gregory XIII. to settle his differences with the Grand Duke of Tuscany concerning the boundaries of their respective States near Città di Castello, and, having acquitted himself to the satisfaction of his employer, died immediately upon his return to Rome in 1573. His remains were deposited in St. Maria della Rotunda, the ancient Pantheon. It was, says D'Aviler, but just that the greatest partisan of ancient architecture should have sepulture in the most magnificent remaining edifice of antiquity. But will not the want of some monument or record there to attest the fact and mark the spot ultimately defeat the intention in his case, as in that of B. Peruzzi and other worthies that sleep there unnoticed by the numerous successive visitants of that august structure?

We are authorised to state that applications for space at the Paris Exhibition of 1900 should be sent to the secretary of the Royal Commission, St. Stephen's House, Westminster, not later than August 20, 1898.

THE ZURICH POLYTECHNICUM.

IT is unnecessary to describe in detail, writes Lieutenant-Colonel Plunkett, this very extensive and splendid establishment for the study of practical science, but the following notes may deserve consideration in connection with the requirements of the College of Science in Dublin. In addition to the extensive building in which the mathematics, drawing and other courses are carried on, two very large separate blocks have been built, one for the physical laboratories at a cost of 80,000*l.* sterling, a second for the chemical and electro-chemical laboratories at a cost of 75,000*l.*, and a third block is now in progress which is to cost upwards of 60,000*l.* for the engineering laboratories. There are also a laboratory for agricultural chemistry, a botanical laboratory, a zoological laboratory, and an astronomical observatory.

There were altogether 1,330 students last session in the institution, of whom 841 were regular and 489 occasional students. They usually come at the age of eighteen or nineteen, and have to pay 100 francs a year, as well as laboratory fees amounting to about the same sum or more. There are between 50 and 60 professors and about 30 assistants as well as occasional instructors, making a total teaching staff of 120. The college is open for 37 weeks in the year; work begins daily at 7 A.M. in summer and 8 A.M. in winter, and continues till 5 P.M. and in many branches till 6 or 7 P.M. I was told that the 200 students who annually leave the college with diplomas have, on account of their excellent training, no difficulty in obtaining remunerative employment at once. A great many poor students are enabled to take the college course by gaining exhibitions.

The different faculties open to the students and the numbers attending each last session are:—1. Architecture, 53 students; 2. Engineering, civil, 178; 3. Engineering, mechanical, 322; 4. Chemistry, with technical chemistry, 154; and pharmacy, 13, as sub-divisions; 5. Agriculture, with sub-divisions of forestry, 30; agricultural engineering, 12, and agriculture, 29; 6. The general or normal course sub-divided into (1) Mathematics and physics, 23; (2) Natural science and chemistry, 27. A seventh faculty consists of a course of science combined with education in general literature and fine arts. I was not given the numbers taking this faculty.

In the engineering school all the students begin with the same course of drawing, mathematics, mechanics, physics, &c., and afterwards take different courses for the civil or mechanical branches. The mechanical engineering students have always a course of chemistry, and in future the civil engineer students will have to take this. Those who intend to be chemists begin with short courses of mechanics, &c.

In the physics department the professor of physics has four assistants and five mechanics in his workshop. There are three courses of lectures, one on physics, one on electro-technology and one on mathematical physics. The students in the mechanical course and those of chemistry are obliged also to take the course in the physical laboratory. The course for mechanical engineers consists of one year at mathematics, machine drawing and chemistry; a second year for physics and mechanics, machine construction and the first part of the engineering course; the third year is devoted to mechanics, machine construction, physics, electro-technological work and the remainder of the engineering course; and a fourth year to electro-technological work, construction and installation of dynamos, &c., and mechanical engineering. The study of mathematics is continued throughout the four years, and at the end of the fourth the diploma is given.

The building for the physics school is 70 metres long and 45 wide, in four floors; there are 81 rooms, large and small, of which 55 are laboratories. There are two gas-engines and five electro-motors with currents from the town installation, which supplies electricity at ·40 per Kilo-watt. In the dynamo-room four groups of students can work at once; there are 20 dynamos, that they may learn all the different types and also every variety of transformers. There is one room specially constructed without any iron, containing large galvanometers and three large balances for measuring currents. Each laboratory has a separate press for apparatus and a separate collection of the apparatus necessary, so that it has never to be carried from one place to another. There is a laboratory for measuring resistance, and another one for work on heat, which will accommodate about 12 students.

Separate laboratories are provided for electrical research, absolute measurements in electricity (where there is a normal chronometer with a pendulum in vacuo), electrical static work, &c.; all the apparatus required for lectures is kept quite distinct from that in the laboratories. There are two lecture-rooms in this department of the college, each for 120 students, and there is a third lecture-room for 60. In the large lecture-rooms the electrical current can be switched either on to one lamp of 900 candle-power or nine lamps of 100 candle-power each. Each student has to go through the work in each laboratory in turn, but they do not go through any workshop work.

The chemical laboratories are well lighted and well ventilated. Each advanced student has 9 feet of working bench and a fume closet; two elementary students are allowed the same as one advanced student. Air is driven into the laboratories by a fan, so that the pressure in the room is always rather higher than that of the external atmosphere. The air is warmed by steam coils in winter, and cooled by water-jets in summer before entering the laboratories. The foul air is drawn off through the fume closets and also by means of two flues in each pier with gas-jets burning in them; high-pressure water is supplied to every working bench, and there is a tap by which this can be converted to low-pressure. Each bench is also provided with a vacuum tube. The chemists generally stay from four and a half to five years in the college, and, as Professor Lunge so forcibly pointed out in his paper read before the Technical Education Congress in London, the whole institution is intended for the education of masters and managers, not of the artisans, for it is upon the scientific education of the former that the industrial future of every country must chiefly depend.

It must be remembered that Zurich is also provided with technical schools for artisans, and that this college is intended for youths whose fathers are able to afford for them this high scientific training from the age of eighteen till twenty-two or twenty-three.

CITY AND GUILDS OF LONDON INSTITUTE.

AT a meeting of the Council of the Institute, held at Mercers' Hall on July 25, 1898, it was resolved, "That the diploma of 'Associate of the City and Guilds Institute' (A.C.G.I.) be conferred upon the following matriculated students, who have completed a full course of study at the Institute's Central Technical College, and have satisfactorily passed the several examinations":—Sydney J. E. Bayly, Edwin A. Byrde, Alfred A. Cahen, William C. Cantrell, Harry K. Chambers, Walter H. Derriman, James H. Dolton, John M. Donaldson, Ernest M. Dowson, Henry A. Dupré, Arthur W. Elworthy, Frederick W. Fawdry, Sydney M. Fowler, Edward H. Freeman, Bertie Glass, Oscar T. Gnosspelius, Alastair M. Grant, Leo Guttmann, G. F. R. Jacomb-Hood, Frederick J. Kimmel, William N. Y. King, Edward W. Lewis, Charles A. McCalla, Guy D'A. Meynell, Joseph L. Naz, Henry A. Neild, Henry W. Oldham, Rowland S. Potter, Herbert J. B. Powell, Ayton H. Read, Richard J. Seligman, Deane H. Slack, Maurice Solomon, Donald M. Stewart, Harold M. Warner, William Waters, William L. Waters, William N. Wilson, Ernest C. Winter, Christopher G. Wright.

PUBLIC HEALTH AND THE BRITISH MEDICAL ASSOCIATION.

IN the section of State Medicine at the meeting of the British Medical Association, Edinburgh, Sir Henry D. Littlejohn (the president) in the course of an address, said he was old enough to remember the former meeting of the Association in Edinburgh in 1875. At that time he was medical officer of health for Edinburgh, where they were busily engaged in two very important works. First of all, they were dealing with the housing of the working classes. There could be no doubt that the old town of Edinburgh at that time was very densely crowded, and Lord Provost Chambers brought in a special Act of Parliament dealing with these areas, and the bill which the city had to pay for this great city improvement amounted to 560,000*l.* Within three or four years there was a marked improvement in the death rate. Of course that involved the transparent fallacy that it represented the total mortality of Edinburgh. But they had their black spots in Edinburgh, as Glasgow, Aberdeen, Dundee, and London had. In these parts of the city the mortality on occasions rose to thirty and thirty-three per thousand, but taking the city as a whole, with its normally increasing population, they had reduced the general mortality from twenty-eight to seventeen per thousand. The other great question that was occupying them when the Association visited them in 1875 was the important subject of drainage. Sir Henry shortly described, with the assistance of diagrams, the various extensions of the city boundaries since 1620 and the drainage and water supply systems of Edinburgh. He thought there was no doubt that they had settled the question so far as the new town was concerned, for they had stocked the water of Leith with fish. There was really no town in which they could study the whole system of drainage better than Edinburgh. Irrigation had been carried on for 200 years in the celebrated Craigentinny Meadows, the rental of which in 1875 had been 47*l.* per acre; within the last ten years it had been 40*l.*, and it was now down to 18*l.* per acre, which compared favourably with the most favoured land in the world. Sir Henry went on shortly to describe the systems of water supply from the Pentlands and Moorfoots and the most recent Talla water scheme, which he believed would supply Edinburgh with a superabundant supply of water. At present they gave an average of 38 gallons per head per day to a population of fully 400,000. They had three peculiarities in Edinburgh. There was their system of daily refuse removal. They had no ashpits. He did not think they could say as much in Glasgow, and, to the eternal disgrace of London, they had there the system of ashpit removal in full vigour. He believed that but for their system of refuse removal there would have been no Edinburgh for them to visit. For the solid refuse so collected they in 1875 received from the farmers 2*s.* 9*d.* a ton, but with the introduction of water conveniences its value was reduced to nothing. They had been driven to erect a destructor, and more destructors must be erected. Another peculiarity was the disgraceful system of course irrigation at Craigentinny. They had twice taken the proprietor of the estate before Parliament, and been twice defeated, because they could never show any mortality. The reason of that was that the population was sparse and that the water supply of the district was that of the city of Edinburgh. Edinburgh, he thought, should be honourably mentioned with regard to the Notification Act. It was melancholy that there had been no great discovery in medicine or surgery but had been violently opposed by their own profession. It was simply disgraceful. The profession to a man in Edinburgh opposed the introduction of the Notification Act. The Colleges of Physicians and Surgeons instructed counsel to opposed the introduction of any clause in any Bill promoted by the city of Edinburgh. Luckily a kind Providence enabled the Corporation to catch them napping; and its Omnibus Bill was quietly passed through Parliament with the fatal clause in it. Notification had been a great success. The mortality in almost every one of the fevers had been diminished, and typhus, which had furnished them with 6,000 cases in one year, had been stamped out. Strange to say, they still found typhus in the sporadic cases that did occur to be as virulent and fatal as ever. But for notification and the way the disease was dealt Edinburgh would again have the unenviable notoriety of a "fever city."

On the motion of Sir Charles Cameron, Dublin, a vote of thanks was passed to the President of the section for his address.

BIRMINGHAM ARCHÆOLOGICAL SOCIETY.

THE last excursion of the Society for the present season took place on the 27th ult., when Cirencester was visited. The company was conducted through the church by the Rev. Mr. Townsend, to whose courtesy and perfect knowledge of the structure they were greatly indebted. The church is one of the most interesting in Gloucestershire. Here are important remains of Norman and Early English architecture, and the base of one pillar is distinctly Roman, having, doubtless, been taken from one of the noble edifices with which Corinium was adorned. The bulk of the church is, however, a fine example of the Decorated style, the body, which is lofty and almost square, conveying a marked impression of space, light and dignity. What restoration has been effected has been careful and reverent, and while the ancient stained glass is admirable, the more modern windows do not compare with it unfavourably. The ancient brasses are great in number and in interest, and the pulpit is a remarkable example of light and elegant stonework. The most singular and beautiful feature of the church is the two-storeyed porch or parvis, the original subject of which is doubtful, but which has certainly been for some four centuries the pride of Cirencester. After luncheon the visitors were permitted to inspect the extremely fine museum of Roman remains collected by Mr. Wilfred Cripps. The chief objects of interest were pointed out by Mrs. Cripps, and include the skull and personal adornments of a Roman lady, who is conjectured to have died a violent death, as her remains were found in the centre of the town, and in no recognised burial place. Outside the museum is the fine capital of one of the columns of the Basilica, a building proved by the recent excavations of Mr. Cripps to have been not less than 300 feet in length and of great dignity. The mosaic pavement preserved *in situ* on the outskirts of Oakley Park was next visited, and after a short glimpse of Earl Bathurst's park, generously thrown open for the enjoyment of the public, the museum built by a former Earl Bathurst for the public preservation of Roman remains was reached. Here are two Roman mosaic pavements, one of them well known as amongst the best and most perfect of its kind in England. There are also valuable Roman tombstones and relics of every kind, from tools singularly like those in common use now to personal jewellery, and the actual bones of the dead. Of the abbey almost nothing now exists except a Norman gateway, which was seen, possessing on the inner side a window through which doles were distributed, and still retaining its glazing of horn instead of glass.

NOTES AND COMMENTS.

The annual report of the Council of the Liverpool Architectural Society announces that the number of members is 131, as compared with 121 last year; the number of fellows is 61, associates 30, students 22, honorary members 18. The increase in the number of members attending the meetings has been fully maintained. In addition to the eight ordinary meetings four members' evenings were held. It is proposed to continue these next session, and it is hoped that more of the younger members may be induced to read papers and join in the discussions. The year has witnessed a change in the abode of the Society. The law library having moved to new premises in Cook Street, the Society has been fortunate in obtaining an agreement with them by which not only will its meetings be held at the new address, but a separate room has been acquired for the sole use of the Society. In this room the books of the library and papers will be placed, and it is hoped that it will be made good use of, and be of value in facilitating friendly intercourse amongst members. A change has been made in the financial year, so that it is now concurrent with the session. The annual subscription, instead of running with the calendar from January 1 to December 31, commences on October 1 and extends to September 30, one subscription thus covering the whole of one session. The most important event of the session has been the celebration of the fiftieth anniversary of the Society. A dinner was held at the Walker Art Gallery on April 18, at which about seventy were present.

Death has removed of late several architects who have aided to embellish Paris by their buildings. M. Deperthes, whose name will be associated with the present Hôtel de Ville, has to be included among them. He died at Rheims in the sixty-fifth year of his age, and his recent plans prove that his skill in designing had not lost its power. The majority of the prominent Parisian architects are natives of the capital, but M. Deperthes was born in Houdilcourt, in the Ardennes, in 1833. He was an assistant of M. Ballu when the competition for rebuilding the Hôtel de Ville was arranged, and co-operated with him in the preparation of the design which found acceptance, and which resembled the former building. Through the kindness of M. Deperthes we were enabled some years ago to reproduce drawings of the new work which is the centre of the municipal life of Paris. His designs were awarded medals at the Salon and other exhibitions, and M. Deperthes well deserved the esteem in which he was held.

It is satisfactory to know that up to the present there is no official declaration about seizing on the masterpieces in Spanish galleries by the Government of the United States as security for the indemnity which will have to be levied. The proposition to imitate Napoleon's conduct is not worthy of a nation that is mainly Anglo-Saxon. Great satisfaction was felt in England by painters when they found that the treasuries of Italian cities and palaces were brought together in Paris. Haydon, Wilkie, West and others rushed across the Channel to enjoy the sight. But the pictures had eventually to be returned, and the memory of the transaction is not advantageous to France. Some of the American newspapers are endeavouring to persuade the Government to enrich New York with Spanish spoils, but the good sense of the country must be opposed to such a revival of vandalism and spoliation.

The causes of diseases are not as yet fully ascertained, but every year there is an approach to certainty. Air, water, food, clothing are according to one theory efficient factors in the spreading of disease. There is little doubt that attention to them has been advantageous. Now it is the turn of the soil. In a paper which was read before the British Medical Association at Edinburgh it was explained by Dr. Robertson, of Sheffield, that numerous investigations are now going on, and it is to be desired that the subject should be put upon a scientific basis. Professor Hunter Stewart was especially mentioned for his researches into the subject. In some experiments which Dr. Maitland Gibson and Dr. Robertson had undertaken, they found that in typhoid planted at a depth in the surface there was noted a tendency to grow upwards rather than downwards. That tendency had a most important bearing on the spread of disease by the soils. A series of maps showing typhoid fever mortality in certain districts in England and Wales was shown. In every town there were to be found small areas in which cases of typhoid fever recurred with great regularity. In one place they had eighteen cases in eight years occurring in eight isolated houses, showing that there was some infected material in the district, and that, with favourable climatic conditions, they had infection growing there and causing disease not only in the houses, but also possibly in other areas in the town. Certain soils in courtyards and around privies into which slops and dirt were allowed to fall were favourable for the growth of organisms. The important question was how the disease organism was transferred from the soil to the man, and Dr. Robertson felt certain that dust was, under certain conditions, the chief agency in the transference of the poison from the soil to the subject. That might be direct or indirect. The practical conclusion was that infectious particles in the air were heavy, and quickly subsided if the air was allowed to remain still. Dr. Robertson was inclined to believe that the Raft theory was the correct one, and if that were the case it went far to explain why only the persons living in or entering an infected area became infected. Such heavy particles would not travel a great distance, but would rather tend to contaminate the food and water in the area.

A paper on a subject that was akin to soils as agents was read by Dr. R. W. D. Macmartin Cameron, viz., on "Surface Wells as a Source of Water Supply." He complained of the Rivers Pollution Commissioners having held the surface well up to general execration as suspicious. Experience has led Dr. Cameron to the view that this important source of water supply has been unduly depreciated. The well must, however, be protected against defilement by a sufficiency of clean ground being reserved around it. Professor Hunter Stewart said part of the water supply of Edinburgh was got from some wells. The deepest of these wells was 8 feet. They were situated in highly manured land. He had seen the water from a "midden" gently meandering over the soil at a short distance from these wells. The maximum number of micro-organisms he had found in these wells was eleven per cubic centimetre. Three of the wells were absolutely sterile. They were not the surface wells spoken of, but they were wells that answered in the affirmative this question:—Can a thin layer of fairly impervious rock protect sufficiently the water underneath it? Dr. Nasmyth maintained it was not the surface well but its surroundings that should be condemned. The difficulty was to get the well surrounded by a pure zone, and if any remedy could be designed by legislation for providing that the difficulty would be removed.

The *Journal of the Society of Archivists and Autograph Collectors* is one of the most interesting of Mr. Elliot Stock's publications. But the condition of the Society is evidence that the search for manuscripts is no more than the hobby of a few. The hon. secretary contemplates the prospects of the Society with something like dismay. There are only thirty-two subscribing members, although the subscription is no more than a guinea a year. The indifference to the Society appears more remarkable if compared with the success of the *Ex Libris*.

CATHEDRAL SERIES.—PETERBOROUGH: NORTH-WEST CORNER OF NAVE.—OLD CLOISTER WALL.—SPECIMEN OF "CHEESE MOULDING" IN CLOISTER WALL.

BURGH HALL, BATHGATE.

The Town Council of Bathgate have under consideration a scheme for the erection of new municipal buildings, including council chamber, burgh court room, town clerk's chambers, and public hall, &c. Our illustration shows the exterior of the design, which has been prepared by Mr. J. Graham Fairley, Edinburgh.

VILLA AT BARTON-ON-SEA.

COTTAGES IN THE ETONWICK ROAD, ETON.

PETERBOROUGH CATHEDRAL.*

IN visiting Northamptonshire for the first time as a society, its members also enter the country which, in the Saxon period, formed part of the kingdom of Mercia. The towns whose cathedrals we have so far attempted to study are situated in districts which formed the kingdoms of the East Saxons, of Kent, of the West Saxons (Wessex) and of the South Saxons (Sussex); and, unless we except East Anglia, it will hardly be possible for us to make acquaintance with any of the other Saxon kingdoms in a corporate capacity.

Thirteen hundred years ago (597) Augustine was sent by Gregory to England to evangelise the Saxon people, in whom he had so great an interest; and it was but twenty years before that event (577) that the battle of Deorham, giving a decisive victory to the Saxon conquerors, caused the Brythons and Goidels (the ancient Britons of our school books) to finally retreat into the country beyond the marshes of Gloucestershire and Herefordshire into Wales and Cornwall. Mercia, then consisting of the counties of Lincoln, Northampton, Rutland, Huntingdon, Buckingham, Oxford, Worcester, Warwick, Derby, Nottingham, Leicester, with part of Hereford and Shropshire, Hertfordshire and Bedfordshire, remained in the hands of the Saxon conquerors, whose paganism was predominant for more than a hundred years after the coming of Augustine to the men of Kent. Not that no attempt had been made to inculcate the teachings of Christianity in the Mercian mind, for missionaries from Ireland, Northumbria and Iona had tried; but it was not until the great St. Finan prevailed upon Penda, the Mercian king, that any real advance was made. The first Bishop of Mercia was appointed by Finan, with Penda's consent, and the king himself and his eldest son, Peada, who married the daughter of the Christian king of Northumbria, were baptised. Penda died in 635, and left five children, who took important parts in the history of Mercia; Peada, Wulfere and Ethelred (sons), and Kyneburg and Kyneswith (daughters).

That portion of the kingdom of Mercia we are concerned with was inhabited by a race of men who were called Gyrvii or "Fen men," very primitive in their habits and impatient of any attempt to improve their condition or surroundings, and it is said that their descendants in the eighteenth century were "still content to stalk on stilts over the fens," as the peasants in some of the rural parts of France do to this day. Strong, tenacious and determined, they were the last to be reduced to submission by the Norman Conqueror in the eleventh century, and how their conquest was effected may be read in Charles Kingsley's famous tale "Hereward the Wake." That charming book should be in the hand of every visitor to the Fen country, for the scene is laid in Lincoln, Burgh (Peterborough), Bourne, Spalding and Croyland. Of the inherest charm of these places I cannot speak here, except to say that it is equalled by no others in this wonderful England of ours.

It would not be expected that a district so desolate in the seventh century would possess such an oasis as the early name of Peterborough suggests, yet Medeshamsted means "the home in the meadows." The venerable Bede mentions it but once; our knowledge of its history is derived from the Anglo-Saxon Chronicle and Hugh Candidus. Bede says, under date 674, that Archbishop Theodore deposed Winfred, bishop of the Mercians, whose see was at Dunwich, in Suffolk, "and in his place made Sexwulf bishop, who was founder and abbot of the monastery of Medeshamsted, in the country of the Gervii." Before his elevation to the episcopate Sexwulf had so far proceeded with the erection of the church that it was dedicated in the name of St. Peter, and so Medeshamsted became St. Peter's burgh in due course and flourished, so that men called it "Proud Peterborough."

> Ramsey, the bounteous of gold and of fee,
> Croyland, as courteous as courteous may be,
> Spalding the rich, and Peterborough the proud:—
> Sawtry, by the way,
> That poor Abbaye,
> Gave more alms in one day
> Than all they.

There are some points of contact here with our visit to Chichester last year. The "Winfred," whom Sexwulf succeeded in the bishopric of Lichfield, was the same famous Wilfred who laid the foundation of the church in the country of the South Saxons; and as the Saxon church of Bosham stands to this day, built nearly a thousand years ago, so does the Saxon church of Brixworth also remain, "in which, perhaps, we still look upon the handiwork of the founder of Medeshamsted." For Brixworth and Ancarig (Thorney) were two cells established by the founder of Medeshamsted monastery, though Thorney now possesses nothing earlier in date than the twelfth century, and if we except its Norman nave and some ancient glass in the windows, is indeed in a sorry plight.

There are some legends of early martyrdoms and miracle-working saints concerning which it is not necessary to say more than this, that the names of the persons concerned are historical, and the legends themselves form part of the interest attaching to Medeshamsted.

Saxwulf's successor in the abbacy was Cuthbald, and he was followed in turn by Egbald, Pusa, Beonna, Ceolred and Hedda; during the last-named abbot's rule the Danes descended in force, and, having destroyed several abbeys in the district and killed the monks, completed their barbarian work by utterly destroying Medeshamsted and slaying its monks, and among them the Abbot Hedda.

For a hundred years or more Medeshamsted remained a waste, till King Edgar in 970, aided by the Bishop of Winchester, Ethelwold, commenced the rehabilitation of the monastery. So lavish were the king and his nobles in their gifts to the Abbey that the town became known as the Golden Burgh, and by this name and its shorter form, Burgh, it was called for very many years, until the more dignified title of Peterburgh became permanent.

At this point it will be convenient to refer to the discovery in 1883 of the remains of a Saxon church *in situ* beneath the floor on the south side of the church. The immediate cause of the discovery was the necessity that had arisen for taking down the central tower and its four piers, when beneath the south-west pier was found a solid structure of wall and cement; this was the east wall of the north transept of the early church, and in due course the west and part of the north walls of the same transept were traced out, together with the entrance and side walls of the choir and the south transept eastern wall. It is understood that the church whose foundations are here traced out is the second one, which was destroyed by fire in 1116; the floor of this newly discovered building showed signs of fire in pieces of charred wood and burnt stone.

So much of the history of the cathedral is of prime importance, we must devote the rest of our limited space to a consideration of the cathedral itself, the object of our visit to Peterborough. Entering from the Market Place through the western gateway, ascribed to Abbot Benedict (1177-95) and containing work of his period as well as later work, we see on the left the Chapel of St. Thomas of Canterbury, now used as a museum, but its condition is no credit to those responsible for its care. On the right are some modern buildings with here and there some piece of the architecture of past times and the gateway to the Bishop's Palace. Before us stands the great west front, called, if the well-worn phrase be excused, "the finest portion in Europe," a description which must send our thoughts to Lincoln, Wells, Lichfield, Amiens and St. Peter's for verification of the assertion. Passing into the nave we see that it consists of ten bays with aisles and west transept. The greater part of the church is of Norman construction, and it may in many points be considered as the most complete Norman cathedral we have. The nave roof is of the most interesting character, painted, as is also the groined lantern roof; the nave aisles are groined also.

The monuments of the church are few in number; though one of them has peculiar interest arising from the doubt with which it is regarded as being correctly described as the monument of Bishop Hedda and his monks. It is a small stone structure 3 feet 5⅛ inches long by 1 foot 2 inches broad, and 2 feet 5¼ inches high. The late Mr. M. H. Bloxam regarded it as "not what we generally understand to be a mere sepulchral memorial, but that it was, or formed part of, some ancient Norman shrine." Certainly its peculiar shape, conveying the idea of a feretory without an interior, favours this opinion, and there can be no doubt that the figures upon it represent our Lord and His Apostles, thus throwing considerable doubt upon its association with Abbot Hedda. The number 870, the date of the slaughter of the Abbot, has been carved on one end, but in very late figures. The interlacing work on the monument is interesting as being a "return to imitation of pre-Norman interlacing ornament which appeared when a new generation of men of Saxon descent began, towards the end of the eleventh century, to find in the arts of construction, &c., paths to the wealth and influence that their fathers lost through the Conquest, and naturally therefore fell back on their methods of ornamentation." (Irvine, Proc. Soc. Ant. xiv. 159.)

There is a very interesting series of recumbent effigies of abbots; the details of dress and ecclesiastical ornament deserve study. The most interesting historical personages connected with the cathedral are Queen Catherine of Arragon, who was buried here in 1535, and Mary Queen of Scots; no monument appears to have been placed over the remains of the former queen, and a brass plate marks their position. So with Mary Queen of Scots, whose body lay here until her son, James I., had it removed to Westminster Abbey, where it now lies in a similar position with regard to the body of Queen Elizabeth that it occupied in Peterborough minster in relation to Queen Catherine of Arragon's remains, that is, side by side in opposite aisles.

* A paper read by Mr. Th. Pitt, F.C.S., on a visit of members of the Upper Norwood Athenæum to the Cathedral.

CONTINENTAL MUSEUMS.

THE report of the Science and Art Department contains the following notes on collections from Lake-dwellings at Lausanne and Zurich, and also on some museum collections in Antwerp, Paris and Brussels, by Lieut.-Col. Plunkett, the director of the Science and Art Museum, Dublin :—

Lausanne.

I spent a considerable time in the museum here examining the arrangement of the collections found in the Lake-dwellings, and inquiring as to the system adopted for making and adding to them. All the sites of these prehistoric dwellings are now covered with water; those of the Stone period are usually not more than about 60 yards from the shore, while those of the Bronze period are often nearly twice as far. No unauthorised persons are allowed to search for objects or interfere with the sites. Those who are authorised to search must bring the objects found to the museum, where they are paid for. They are arranged in the museum by stations, the objects from each place being kept together, which is probably the best method to adopt in the case of these finds.

A considerable number of wooden hafts of various implements have been found; these are preserved in the Museum with glycerine. In the Dublin Museum the wooden objects which have been found in the bogs and crannogs have in many instances suffered from not being properly preserved; paraffin wax is the material which I had hitherto considered the best for this purpose, but it will evidently be a good thing to try some with glycerine, as at Lausanne. One curious find is a kind of cake made of some sort of meal, and containing acorns stuck in it like almonds; this was contained in a broken earthenware pot, in which probably it had been cooked. An arrangement should be made for getting some small collections of the principal types of implements found in the lakes of Switzerland to place in the Dublin Museum for purposes of comparison, and similar small type collections of Irish antiquities might be given in exchange.

Zurich.

I was disappointed on arriving at Zurich to find that the National Museum of Swiss objects is in process of removal from the old building to a new edifice which has been erected near the railway station, which also contains a small museum of industrial art and an art school. The prehistoric collections have been already removed into the new building, and a great part of them has been arranged, but not the whole. The Lacustrine objects are from the collections of M. Grosse of Berne, and the articles are laid out generally in classes, each type being placed separately. For instance, the first case contains piercers made of deer's horns or of bone; the second case contains cutting implements, weapons and tools of the same material; after these come hatchets and hammers made of horn, and also hoes or small digging instruments made of deer's horns, and so on. The collection of copper and bronze implements is also interesting, there are many fine swords, and several objects possess interest as bearing upon the question of the channel through which certain varieties of ornament, and presumably certain arts and handicrafts, have been introduced into Ireland.

The cases in which the above-described collections are exhibited are generally high, with pyramidical centres covered with cloth or built up with shelves in stages; the colour of the cloth is generally terra-cotta, and forms a good background to the objects. The rooms are vaulted and have pillars down the middle; but notwithstanding this I found the lighting good, though I visited this collection in dull cloudy weather.

It is difficult to express within reasonable space the many useful lessons that are to be learned from inspection of these collections from the Lake-dwellings of Switzerland. In the first place, it is impossible to exaggerate the very great advantages derived from regular and authorised systems of search. If the many objects which have been so carefully collected from different sites had been gathered by unauthorised persons and placed in private collections, without any proper record of the places or the depth at which they were found, and then transferred to the National Museum when information as to their history was no longer obtainable, the great work which has been done in elucidating the early history of civilisation, the movements of tribes and races, and the direction of trade routes in early times, would have been absolutely impossible.

It is to be hoped that the good example set in Switzerland, as also in Denmark and Sweden, will in future be so far as possible followed out in our own country, and that people will see that information regarding the surroundings of a find and the circumstances under which it is discovered are often, one might almost say always, just as important as the objects themselves.

In the second place, it is evident that the plan of keeping the finds from each site separately is on the whole the best that can be adopted. It might at first appear more scientific to take all the objects of any particular class or period and put them together wherever they may be found, as in fact must be done when forming a series to show the progress of manual arts and of civilisation, but in this instance the history of each particular site should itself be investigated as far as possible; and with this object it is evidently better to display all the objects found in it in a regular series, keeping them as far as possible in positions corresponding to the layers in which they have been found, from the earliest and most deeply buried portions to the most recent. By this means of comparing the series of objects found in any particular site or crannog with those in a complete series it is possible to make some approximation to the history of the site and the periods during which it has been inhabited.

The presence of implements made of flint, nephrite and other minerals which are not found in Switzerland opens up interesting questions as to the traffic between various tribes at that remote epoch, and may assist materially in deciding as to what were the principal trade routes employed. In the same way a finding of beads or other objects made of amber and of implements of decided Scandinavian pattern is, of course, evidence of trade with the nations inhabiting the shores of the Baltic Sea.

It is very interesting also to note on what lakes and on what routes only chipped-stone implements are found and were used. A comparison of the accuracy of the workmanship of the various kinds of implements found here with those found in Denmark, Sweden and Ireland has given to antiquaries some idea as to the length of time during which the several stages of civilisation lasted in the respective countries.

The extent to which copper implements were used before the introduction of bronze is another interesting point to note, in connection with which Mr. Coffey has suggested a careful analysis of the material used in various Irish implements; and so is the persistency of certain types of ornament which at some period seem to have been generally diffused over a great part of Europe, and at the same time the complete absence of other well-defined types which are so common along the Mediterranean and West of Europe as far as Ireland.

The several varieties of the three principal types of bronze axe-heads, and also the varieties of hammer heads are interesting for comparison with our own, and so are the small bronze sickles with their well-worked and well-defined ornaments of a somewhat unusual pattern.

The implements of what are called the "La Tene" period, and the modifications which they have evidently undergone by the influence of Greek and Roman art, will assist in determining how far objects found in other countries have been modified by the same influence.

Mediæval.

In the same building with the Museum of Antiquities are the Mediæval collections. This portion of the museum is divided into a large number of rooms, each of which is generally finished as a facsimile of an existing portion of some typical building, though, in a few instances, only a ceiling or portion of the room has been copied.

Taking the rooms in order I made notes of the decorations, and from these I select the following as of more importance than others :—

1. A ceiling near the principal staircase, copied from a church at Zillis, of the twelfth century, and an arcade of moulded bricks, copied from some fourteenth century ones at Beremunster, St. Urban and Zofingen.

2. A copy of the Council Chamber at Mellingen built in 1467. The arms of the Swiss cantons are in the windows; the old door is interesting, and especially the ironwork, of very unusual pattern. A drawing of this would be useful.

3. A small room which was that of the Abbess at the Frauminster of Zurich of the year 1487.

4. The next room was that of her successor in the same building, and was decorated in the year 1507; the decoration in both these rooms, Nos. 3 and 4, is very fine indeed, and when the museum is complete they will be fully provided with furniture of the proper period.

5. Oetenbach room, from a nunnery of the year 1521, which is now a prison; this room contains a splendid tiled stove of the year 1638 brought from the Canton of Berne.

6. Pestalozzi room, from Chiavenna of the year 1585; the inlaid panels, and in fact the whole of the decorations of this room, are exceedingly beautiful, and so is the stove in it of the same period.

7. Seidenhof room, of the end of the sixteenth century, containing a very fine tiled stove of the year 1620 from Winterthur; a massive four-legged table standing on a base or daïs is also remarkable; and the panelling both of the ceiling and walls, original and in excellent preservation, is very good indeed.

8. The room of Lochmann, who was a general in Zurich, of the year 1715; the panelling of the walls is good, the frieze consists of a series of portraits, and the ceiling is in large panels painted in figure subjects. The stove is good, and an iron balcony and balustrade which have been removed and

placed here are very well designed as well as the lock and hinges of the door. There is an iron screen in a chapel, and a considerable number of the tiled stoves made in Winterthur, generally by members of a family named Thau.

At present there is very little furniture in any of the rooms above described, but it is intended to put in them furniture and other objects of the same periods as the architecture and decorations of the rooms. By this means a historical museum will be formed in which the public will be able to see the state of the decorative arts in every department in different parts of Switzerland at various periods. In this way there will be carried out the same idea which governs an important branch of the large museum at Amsterdam, and also the smaller museum in the Steen at Antwerp and in the Rosenberg Palace at Copenhagen. I think that the advantages of this system in educating the taste of the general public and in interesting them in museum collections are evident.

The main building is constructed as a mere shell, and then additional partition walls, ceilings and other parts are constructed of lath and plaster and other light materials, to reproduce exactly the interiors of the old buildings which are copied. Had the museum been designed so that the interior should produce a handsome architectural effect, this would, of course, be almost impossible, and in any case would have entailed great waste of money.

As above stated, the rooms are at present mostly empty, or nearly so; but the ceilings which have been fixed, the tiled stoves and the fine wrought-iron work are well worthy of careful inspection; and, doubtless, when the rooms and collections are completed, this will be one of the most interesting museums of the kind in Europe.

The Museum of Industrial Arts, or Gewerbe Museum, is in the adjoining building together with the School of Art. In it there are exhibited only such objects as are considered to be especially useful for art students; there are large numbers of specimens of textiles, each piece is framed as a panel, and the large panels will each contain two or four of the smaller ones. These specimens are frequently changed and replaced by others which are kept in store. There are some specimens of Zurich silversmith work, but nothing else particularly worthy of notice.

In the School of Industrial Art there are both day and evening classes for drawing, painting, carving, photography, designing, &c.; the students attending the day classes generally go through a three or four years' course; the evening classes generally consist of young persons employed during the day, and they study for designing lace, furniture, porcelain and metalwork. I could not see the master of the school, but only the curator of the museum.

Antwerp.

I visited the Historical Museum in the Steen, which is a Mediæval fortified building used for many years as a prison. There are Roman remains and other antiquities, but the most interesting articles in the collection are some very good examples of Mediæval ironwork, bedsteads and other woodwork carved in Flemish style, some fine carvings from the ceilings of houses which have been pulled down, a good many brackets carved with coats-of-arms, some fine cast-iron fireplace backs, a quantity of Flemish, Venetian and other glass. The collection is not a large one, but it is well worth while to stop a day in Antwerp for the sake of seeing it.

Brussels.

In the museum buildings there is a fine collection of early and Mediæval art, which is very interesting in many respects for comparison with objects in our collection in Dublin. The following objects are particularly worthy of notice:—A mounted horn ornament with panels and recessed ornaments peculiarly like much of the ornament on the Cross of Cong, a similar likeness being discernible in the ornament on the stem. I could not get any photographs of this object, but a drawing of it has been published. Some carved walrus tusks found by the Meuse, the incised decoration on which shows a very curious mixture of styles; it seems most probable that these are of Norwegian origin, and brought southwards as articles of barter; some very fine early enamels, more especially a small portable altar of the twelfth century. The tapestries, as might be expected in this country, are remarkably fine, many of the pieces of the sixteenth-century manufacture are quite exceptional; and one of these, worked in wool, silk and silver thread, is perhaps unequalled elsewhere. A very interesting part of the museum consists of a suite of rooms fitted up for the King of the Belgians, and decorated throughout in Flemish style; the fireplace, doors, furniture and ornaments in each room are of one period, so that the different styles may be studied and compared.

Paris.

As the Louvre and Cluny Museums are so well known, I have noted only a few points which I noticed for some special reasons. The Cluny Museum is rather overcrowded, but the collections here have the great advantage to the general public of being exhibited in rooms built and decorated in styles which harmonise with that of the contents. The carvings, tapestries and embroideries are remarkably well shown. A very good carved chimney-piece from Rouen would, I think, be well worth reproducing, as also the splendid wood panels which are shown on screens in the same room, No. 3, on the upper floor.

Louvre.

One of the things that struck me particularly in the room devoted to Persian antiquities was that the frieze of the room itself is painted to show the landscape of the country from which the antiquities are brought. For our architectural collection large photographs of the model which represents a restoration of the Apactana, or throne hall, of the ancient Palace of Susa would be exceedingly useful, as the details are all taken from the actual remains. Among other antiquities, the necklet, earrings, cap and other objects found in the tomb of a woman at Olbia, which are of marvellously fine workmanship, are among the most remarkable, and if reproductions cannot be obtained good photographs would be useful.

Musée Historique.

The most interesting part of this museum consists of the rooms themselves, which have been carefully restored. It appears to me that no better models could be found for courts to contain French furniture than the room which is known as Le Salon Louis XIV. and the central part of the Salle de la Revolution. The walls are panelled and the ceiling is painted.

Guimet Museum.

This is a new building of two storeys; the upper floor is well lighted, but the ground floor is very defective in this respect, and at four o'clock in the afternoon it was very difficult to see the objects properly. The collections intended to illustrate the theology and mythology of various races consist in great part of Chinese and Japanese objects—one Chinese table in brown lacquer of the fifteenth century is particularly worth notice; also a number of rock-crystal vases and objects in jade. A very good specimen of bronze-work is a large four-armed figure in a wheel surrounded by frames and the hair standing out like wings. Irrespective of its value to students of mythology, it is a very fine piece of workmanship.

Garde Meuble Nationale.

In the two large rooms devoted to Louis XIV. and Louis XV. furniture the many very fine specimens of work of the best makers give good standards of comparison.

THE PAPYRUS.

THE publication by the Egypt Exploration Fund of about one hundred fragments of papyri through the agency of the Clarendon Press has renewed the interest in the ancient use of a material without which it is difficult to understand how civilisation could have advanced. The Fund was able to secure between five and six thousand documents in Egypt which were inscribed on the prepared leaves of the papyrus plant. They are not all of political or literary importance, for some relate to commonplace affairs and the ordinary transactions of everyday life. But there is undoubted interest in the discovery that over two thousand years ago life in Egypt bore much resemblance to life in England at the present day.

While giving attention to the biblical sayings, stanzas from poems and dramas, legal forms and other matters which the papyri furnish, we must not be indifferent to the material which has been of so much use to ancient writers, as well as to ancient ornamentists. Something is known about the papyrus, but not all that is desirable.

The literary history of the papyrus, says De Vriese, as of all the other plants of the ancients, has been divided into three periods. To the first belongs the series of writers anterior to the time of Alexander, who, by mentioning the name of this plant, have contributed to its history; but the work of Theophrastus is the most important in this period, the most ancient, and at the same time the best Greek botany that has reached our days. He treats briefly and circumstantially of the plant in question. Dioscorides mentions it cursorily, and lauds especially its healing powers; and other writers have followed his example, even to the pharmacologians of the seventeenth century. Besides Dioscorides, many other ancient writers have given no unimportant information on its history; for example, Herodotus, Diodorus Siculus, Strabo, Lucan and Plutarch. Pliny, however, is generally considered to have given the best account of it in the thirteenth book of his "Natural History." It is also mentioned in the Sacred Writings, in the books of Job, Isaiah and Exodus.

The second period of literary botanical history, so far as concerns the plants of the ancients, begins with the revival of letters. This is, perhaps, taking into consideration the few

advantages which then existed, to be called the brightest period of science, even our own not excepted. He who is acquainted with what was effected in the sciences at that time, must at all events readily allow it, especially if he be intimate with the works of Alpinus and Aldrovandi, the schools of Pisa and Florence, with Rembert Dodoens (whose real name was Jankema Friso Van Staveren), Charles de l'Ecluse, Matthias de l'Obel, Cæsalpinus and the brothers Bauhin, so learnedly immortalised by Linnæus, correctly called the great botanists of that day. Whoever reflects on the almost unsurmountable difficulties against which they had at that time to strive, may conceive the zeal with which they laboured, and be astonished at the 'Pinax' of the youngest of these brothers, that colossal work which comprehends a complete account of all that had been effected in the science up to that period, the progress of 2000 years. The writings of the ancients, particularly those of Dioscorides, were the text-books, and all the botanists of every country employed their endeavours and powers in their illustration, endeavours which, at that time, were the more useful to be acquainted with, when authors first ventured to regard the opinion of the ancients no longer as infallible, and to doubt their authority. Thus originated, along with many others of the same kind, the learned work of Matthiolus, a work which has been constructed in a manner quite inconceivable, and with incredible zeal. It has been reprinted thirty times, and is very important for the inquiry regarding the papyrus of the ancients.

Pliny's remarks on this plant have been especially explained, contradicted, and again defended, by the writers of the fifteenth and sixteenth centuries; by some his credibility has been doubted, by others—and particularly by the grammarians—it has been highly extolled; among the former is the famous Melchior Guilandinus (properly Wieland), who travelled in the Levant in 1559-60, and who, some years later, when professor at Padua, published as the result of his researches a commentary on the papyrus, which, according to the testimony of Mabillon, became rare in the beginning of the eighteenth century. Scaliger defends Pliny against Guilandinus, and he again is defended by Mabillon; Salmasius has also taken up the sword against him. But without noticing other commentators, we shall proceed first to speak of the names of this plant.

The papyrus, like almost all other products of nature, the names of which alter by the increase of the knowledge of species, has received various appellations, and the word itself is applied to more than one object.

Before the time of Theophrastus we find the term papyrus used especially by the poets for the plant itself, and all things made from it. It remained in use many centuries after the commencement of our reckoning and after paper had ceased to be made of it, which has occasioned great confusion in many writers; Salmasius has already protested against the use of the word papyrus for "charta." It is nothing strange to give the same name to a substance and the productions made from it; but it certainly is so to apply the name of papyrus to articles that have nothing at all to do with it, either in their origin or manufactory—it seems erroneous to call our writing paper "papyrus" or "papier," which is made of rags, as if it came from the plant which served for its composition in Egypt. The name papyrus was, in the first place, given to the plant itself; next to the outside layer of the stalk, to the uppermost part of the stalk, also to the outward covering of the stalk which was used in making paper, called likewise "philura," and to the paper when ready for use. The root also had the same name, as well as cordage, sails of ships, wicks of lamps, and clothes made from it. Does not the retention of this word in many diplomatic transactions even to recent centuries indicate that this sort of paper has been much longer in use than is generally supposed? So late as 1304 the term papyrus occurs in a decree of Philip le Bel, where the notary is enjoined to write upon good papyrus. Many authors of more recent date attest its long-continued use for various purposes. The words "charta papyracea," in use among Latin writers, naturally mean nothing but paper made from this plant.

There are many opinions as to the etymology of this word; some derive it from the Greek, others from the Coptic. Scholz is of opinion that it is a Coptic word, composed of "bir," to weave, and "pa," the name of the plant. This certainly presumes very great antiquity, and a very ancient use of it. Scaliger has derived it from the Greek. Bernard de Monfaucon is of opinion that the word is derived from the Egyptian, which would in some measure prove that the plant is of Egyptian origin.

The word "papyrio" signifies with many writers, and especially with commentators on the Scriptures, the place where this plant grew; it is not, however, in common use. The name, found in many authors of later date, naturally stands in connection with its place of growth. Prosper Alpinus calls it in Egyptian "berd," and he has been followed by succeeding authors. Whether Alpinus be worthy of credit in this portion of his work is doubtful; he is, with regard to this plant, very short, incomplete and inaccurate, and copies the errors of Pliny.

The Hebrew name "gomè" has been explained by Olaus Celsius as meaning "paper-rush," or "paper-plant." Earlier commentators on the Old Testament understood by this word every sort of rush or cane in general; but this interpretation was overthrown by Celsius, who, by a comparison of all the passages in which it is mentioned, has proved that the papyrus is meant and no other plant; it is believed he was the first who promulgated this opinion, and it has never since been contradicted.

The name of "biblos," given by the Greeks to this plant, is perhaps not less ancient than that of "papuros," and certainly as often used, especially by the poets. Theophrastus and all older and later writers used the word as synonymous with "papuros," to denote both the plant itself and all the articles manufactured from it. In process of time, it came to be applied to every sort of material used for writing upon, as the history of the progress of that art teaches us. Whether Theophrastus really meant by "biblos" the interior of the stalk (cortex interior vel liber) in opposition to "papuros," the exterior (cortex exterior vel cortex), as has commonly been supposed, is uncertain, because the papyrus has no bark either external or internal, which distinction of bark and bark-fibres or layers was made even by the ancients themselves (so far as applies to ligneous plants), according to commentators. The Latins also gave the name "biblos" to the plant, but although occurring in Lucan and other poets the word does not seem to occur in the best prose writers.

Figures of this plant have already been given by the oldest commentators on Pliny and his predecessors, but they have evidently just copied each other; for example, Alpinus, L'Obel, Morisson, Matthiolus, Scaliger, Chabræus, Micheli, Boccone, Scheuchzer and many others. They are generally bad, with few exceptions—indeed, so much so that the authors do not seem to have the smallest knowledge of the plant.

According to Pliny, Egypt was the country where the papyrus grew. This fact is quite indisputable, and can be confirmed by the best testimony; and an inquiry instituted in our days would show that there was yet a great deal of truth in the statements of Pliny eighteen centuries ago; most probably it would decide that Egypt was the original country of this plant; but we shall seek the solution of this question from what its own history teaches us.

We shall view it then first in Egypt; it grew there in the stagnant pools formed by the Nile from its annual inundations, and also in marshes. From this account of Pliny, which is certainly very indefinite, we are perhaps right in conjecturing that the plant was there very common (as the Nile ran through the whole of Egypt, emptying itself by seven mouths into the sea), which opinion there are many other reasons for believing, as the epithets generally applied by the poets to the Nile, "amnis papyrifer, Nili alba tabula, papyriferi septemflua flumina Nili," &c. It thus grew in shallow places. In this Pliny follows his predecessor Theophrastus. "But the papyrus does not grow in the depth of the water, but in about two cubits, and sometimes even less."

Pliny quotes from Varro that the papyrus plant was first seen in Egypt after Alexandria was founded, the probability of which he himself is rather inclined to doubt; and mentions in another passage that Varro is contradicted in this point by many other authors. Indeed, it is difficult to suppose that a people, who before the time of Alexander must have been so highly civilised, and had made such remarkable progress in the arts and sciences, could have been ignorant of one of the most useful plants which Egypt produces.

Two difficulties especially present themselves here. When was this plant first known in Egypt; and at what period was writing paper first made from it? The last question is still incapable of solution, and it is perhaps the most difficult in the whole history of the papyrus. Owing to the incompleteness of resources, it is no easy matter to decide at what epoch any important discovery has taken place among an ancient people. With regard to the first question, we can come to a more accurate conclusion than Pliny, who in this portion of his work is found fault with by no one more than his commentator, Melchior Wieland, or Guilandinus. He proves from a number of authors before this time that the papyrus must have been known many centuries earlier, as Æschylus, Anacreon, Alcæus, Herodotus, Homer, Plato, and others have all mentioned this plant at an earlier period.

It is also remarkable that Pliny says that Homer, through whom we learn that tablets or pocket-books (which were probably of wax and written on with a stylus) were used even before the Trojan war, could not have known the paper plant, nay, even, that the whole of Egypt then could not have understood its use; and although we give to the words of Pliny the meaning which Scaliger applies to them, we might still find a proof against what that celebrated writer has communicated to us concerning the era of the discovery. Though Homer did not know Egypt as it existed in the time of Alexander, the

whole of Egypt was not unknown to him, as we see from many passages in his poems. The Nile also runs in the older part of this country, in Ægyptus Superior, or Thebais of the ancients, which was mentioned by Pliny as the habitat of this plant; besides, Homer has noticed the plant, or rather, the productions made of it.

To define more closely what he at first had mentioned generally, Pliny proceeds to remark that this paper-rush only grew in the Sebennitic district (so called from the city Sebennus), which is in the Delta, which originated from inundation, and thus formed a part of Egypt. The word Sebenniticus in the text of Pliny has without sufficient reason been altered by Guilandinus to "Saiticus," but again restored by Scaliger, who thinks the reading is, when literally translated, "since at least in the district of Sebennys nothing but the paper plant grows." The remark of Pliny amounts to this:—There was no Ægyptus Inferior in the time of Homer, much less still was the plant there which grew there afterwards. There is more than one reason to believe that Homer knew of the Delta. If we hold it recorded in the "Odyssey" that Menelaus, after the fall of Troy, was driven by a storm on his passage back with his queen to his own kingdom, on the Egyptian coast near Canopus, where one of the seven mouths of the Nile was, then the Delta, where this city stood, could not have been unknown to him. If the papyrus was principally found on ground originating from inundation, then there is still greater probability that Homer was acquainted with it, because we in that case derive the origin of the papyrus from Ægyptus Superior, or even perhaps from more southern parts of Africa.

Besides the works of the classical age, we find also in the Old Testament a higher antiquity for the papyrus than Pliny would ascribe to it. In the 18th chapter of Isaiah, verse 2, not only according to Celsius, but also according to Hitzig, mention has been made of vessels of the paper plant. This prophet is said to have appeared in the year that King Uzziah died, about 759 B C. He mentions also the seven mouths of the Nile, chap. xii. v. 15, and thus knew the Delta. In the writings of Moses, we have perhaps no less strong proof of the antiquity of this plant belonging to a period long before Isaiah. The Pentateuch, in which this plant is mentioned, carries us back to a much earlier epoch. In a basket or boat of paper-rushes, as the historical relation purports, this famous child was saved from threatened peril, who was to be the greatest law-giver of the people of Israel. Brought up in Egypt, acquainted with Egypt, knowing their arts and institutions, Moses could not have been ignorant of the use of this plant; might he not even have written his Pentateuch upon the Egyptian papyrus? Winckelmann supposes that the books of Jeremiah were also written on the papyrus. In confirmation of this, it may also be adduced that Horapollo has mentioned that this plant was there used as the symbol of antiquity. We are aware that the Athenians represented the antiquity of their race by the symbol of a cicada; nor is this sort of symbolical representation strange in history. Who does not recollect the fable of Tithonus, the immortal grey-haired consort of Aurora?

Against the remarks of Pliny, it can be contended that—1. This plant, although a native of Egypt, has not yet been observed in that part of the country which has been known under the name of Ægyptus Inferior. 2. That Homer has known and mentioned this plant, as well as many others beside him, before the time of Alexander, and that therefore the use of it belongs to a much earlier period.

If we trace the multifarious uses of the papyrus in Egypt, we may thus prove that it must have been found in very great abundance. Dioscorides says of it:—"The papyrus is universally known."

It was previously quoted from Theophrastus and Pliny, that the paper plant grew on spots where the water was not deeper than two cubits, which agrees with the remarks of later observers. It chooses a moist marshy soil; in our climate it grows very luxuriantly in pools or cisterns, in moderately warm summer weather. The root (properly a stalk), which elongates itself in a slanting or horizontal direction, and develops new parts, is as thick as the wrist, which is literally what Theophrastus states. The stalks, as mentioned by Theophrastus and Pliny, are triangular, which agrees exactly with our knowledge of this plant. Bundles of papyrus stalks in museums confirm still more the statements of the ancients, in addition to other abundant proofs.

Pliny mentions that the papyrus never grows higher than 10 cubits, in which he has incorrectly translated Theophrastus. If, as he says, the root becomes longer than 10 cubits (as may be readily believed, this being a peculiarity of the root of many rush-like plants), and that the triangular stalks attain a height of 4 feet, then Pliny reverses this, and says that the stalks never reach a greater length than 10 cubits, a length which no one has yet seen in them. Guilandinus, who travelled in Egypt, never saw them longer than 7 cubits. Alpinus speaks of a height of 6 or 7 cubits above the water. If we suppose 2 cubits under the water, then we are not very far from what Pliny has incorrectly translated from Theophrastus. Veslingius, the commentator of Alpinus, confirms this observation.

Pliny mentions that this stalk encloses the summit like an oval cluster; but almost all commentators attack him on this point, and his meaning is not very plain. He is accused of having erroneously translated from Theophrastus, and, as far as we can gather from our knowledge of this plant at the present day, has asserted what was not intended. Theophrastus says, "having a useless weak down," and Pliny takes this as a characteristic of the yet undeveloped leaf or the summit; and if we take his words in this sense we see no reason for assuming the emendations of Scaliger in this passage or approving of the invectives of Guilandinus. The expression of Pliny could not, however, be improved. When we look at the smaller stalks of the plant we see on their summit the oval clusters or thyrsi, formed by the tufts of hair-like or fibrous leaves, still enclosed, and lying against each other, while they include the undeveloped flowers. This down or sheath was certainly not wholly useless, or at least unused, as we learn from Pliny and other sources, and the inspection of Egyptian mummies, but being esteemed as very beautiful, was used to ornament the statues of the gods and the heads of the deceased; the fragrant lotus, however, has been more generally found in mummies than the umbellæ papyri.

The third period of the literary botanical history of the ancients extends to our own time. Never, perhaps, did so many means exist of correctly investigating the plants mentioned by the ancient authors as at present. The great circuit of botanical science has brought this portion of knowledge to a degree of accuracy which could not previously have been calculated upon; the increasing knowledge of the geographical distribution of plants has advanced to such a wonderful degree, and the writings of the ancients have become so much better than ever interpreted and understood. If natural history and literature would but join hand in hand, one of the fairest periods of the history of science, which has long been enveloped in the deepest darkness, would come to light in all its dignity and simplicity. We should no longer see partiality and ignorance displayed by the one as well as the other in commenting on and illustrating the works of antiquity. Whoever thinks differently may enjoy his own opinion; he knows not perhaps what a Sprengel has already discovered, nor what has resulted from the inquiries of a Dureau de la Malle into the ancient Egyptian Cerealia. Lyngbye, Bonastre, Trattinnick, Sternberg, Fee, Tenore and Desfontaines have shown us how to set to work with most chance of success in researches of this nature.

The papyrus has been more written about in our time than minutely investigated; no one at least appears to have given his attention to this plant especially; a strange phenomenon surely, when Egypt in our time, more than any other country, we might almost say, has been exhausted by researches of every kind, and all sorts of learned inquirers; all, however, are silent about the papyrus, as if such a plant had never existed, or very cursory notice is taken of it, as a thing of no particular importance; or sometimes it is mentioned in a way which would almost cause a doubt of its ever having existed. Some notice of it might have been expected from the French savants who examined Egypt during the campaign of Napoleon; but in their great work on that country the name of this plant is only slightly touched upon, and nothing at all of its history. Since then archæologists have too much busied themselves to make out the written state of the papyrus, considering the inquiry into the matter itself, as it appears, of less consequence.

Is the papyrus still in Egypt? To this question we may answer, that those who should make mention of it pass it in silence. Has the assault of time here on this spot destroyed this remarkable product of nature, and is it no longer produced in this whilom so fruitful, so civilised Egypt?

According to Salt and Drovetti, it must still exist in the Delta. Minutoli found it on the marshy banks of the Phatnic Uylarus, and other canals in connection with it, flowering in August and September, agreeing perfectly with the description given of it by Linnæus, Willdenow, and the Count Henkel von Donnersmark. Minutoli says, "The papyrus plant, or the so-called cyperus grass, is found very rarely in Egypt, and peculiarly in small quantities in the district of Damiata." Landolina saw the papyrus in Egypt, as is mentioned by Bartels. Bruce has seen it in Upper Egypt and Abyssinia, in marshes formed by the overflowing of the Nile, where there was no reflux, and the water remained. Reynier mentions that the naturalists of the French expedition only found it on the banks of the lake Menzaleh. Ehrenberg does not appear to have discovered it. Minutoli asserts, though incorrectly, that Delile also did not find the papyrus, on the ground, perhaps, that he has not described it circumstantially in his "Illustratio Floræ Ægyptiacæ;" that author mentions Damiata as its habitat. Forskäl passes it over in silence, but perhaps he never reached the spot where the papyrus grows; it was Lower Egypt which he principally examined. Bovè, who enjoyed the most ample opportunity of examining the country,

found many Cyperaceæ; but has not hitherto, among his Egyptian plants, taken the slightest notice of the papyrus antiquorum. Rüppell has not detected it on the banks of the Nile, and although Bruce found it there he rather supposes that it is now a very rare plant in Egypt, although it must be regarded as a native of that country, and that Abyssinia equally deserves that distinction.

If we trace the cause of the decrease of this plant in Egypt we need not be surprised at its disappearance. Pliny has already in some measure made us understand this, and Strabo (xvii.) relates that the Egyptian Government, the better to preserve the trade in papyrus, resolved to root out all the plants to a certain point in the Delta. The export of this article was so great that it formed the principal part of Egyptian commerce, and was one of its greatest sources of revenue. Flavius Vopiscus mentions that the rich merchant Firmus could maintain a whole army on his returns from this trade. It is probable also that the Egyptians made this plant an object of culture, otherwise in a few years it would have disappeared from the whole land. If, in addition to the reasons already given for the disappearance of the papyrus in Egypt, we consider the alterations which the course of rivers and the condition of a country must undergo in the lapse of centuries, the changes which must occur in the distribution of plants (particularly the aqueous), we may thus more correctly account for the remarkable variation of the present from former times.

The paper plant of the ancients, however, is not so rare as some have said, for when Guilandinus was in Egypt, about two centuries since, the pith was then used as food; in 200 years a plant so easily cultivated along a considerable river would not readily die out, especially by a lessened use of it.

The family of the Cyperaceæ have this property in common with the Gramineæ, that the plants belonging to them are found in all climates and nearly in all parts of the known world; of the peculiar genus papyrus belonging to that family there are species in all parts of the globe. It is not to be met with in the interior of Italy, or else it must have been seen during the many researches into that country, particularly by Tenore. It is found, however, in Syria, Ethiopia, Abyssinia, on the Euphrates at its junction with the Tigris, and on the Jordan, also in the Isle of France, in Madagascar and in Sicily. De St. Non has given a full account of the Sicilian papyrus, with good figures. Willdenow obtained the ripe seed from this island, which has sprung up in the garden of Berlin. It there never reaches the height which Pliny ascribes to it. Micheli asserts that he has found the papyrus growing wild in the marshes of Calabria; other observers, as we have mentioned above, contradict this. Sibthorp did not see it in Greece.

It is now to be met with in almost all botanical gardens, and appears to have been brought from Egypt to Italy, and from thence to other parts of Europe. When this plant became an object of historico-botanical inquiry it soon became better known. It is mentioned among the plants in the garden of Pisa in 1677, as brought from Egypt; and in the garden of Florence in 1729, brought from Sicily; and previous to 1740 it is mentioned as being in that of Leyden.

PICTURE SALES AT THE ACADEMY.

ARTISTS who are exhibiting this year at Burlington House, says the *Westminster Gazette*, must find but small satisfaction in consulting the sale catalogues which are spread out on the little tables in the vestibule, for the sales at the present exhibition compare very unfavourably indeed with those o 1897, which was not itself by any means a prosperous year. It is difficult to account for this falling-off, for a cold, wet early summer like that of the present year is always beneficial to the exchequer of the Royal Academy. When the weather is fine and warm the Londoner at leisure naturally prefers to amuse himself out of doors, reserving chill and rainy days for the Academy and kindred institutions. This year there were many inclement days in May and June, and an unusual number of shillings were therefore paid at the turnstiles of Burlington House.

It might well be supposed that the sales of the pictures would bear some relation to the number of the visitors; but this, unfortunately for the artists, has not proved to be the case. To the Academy itself the season has been a prosperous one, but the entire amount realised by the sale of pictures up to July 15, by which time the sale season is practically at an end, was only 13,730*l.* 18*s.*, against 16,384*l.* 15*s.* in the corresponding period of last year.

Yet, curiously enough, though the sales, taken altogether, are disappointing, they show in one department a marked improvement upon 1897. This is in the Water-colour Room, where seventy-five drawings have been sold for a total sum of 2,005*l.* 17*s.*, while last year only fifty-six were disposed of for 1,282*l.* 17*s.* The prices of the sold pictures in this room range from 3*l.* 3*s.* to 162*l.* 15*s.*, the last-mentioned sum having been given for Mr. Archibald Thorburn's drawing the "Home of the Golden Eagle." Other water-colours which have realised more than a hundred pounds each are Mr. H. M. Rheam's "Quia Multum Amavit" (110*l.*), Mr. Tom Lloyd's "By Misty Stream and Meadow" (105*l.*), and Mr. Alfred Glendenning's "Haymaking," which the Chantrey Trustees have acquired for 157*l.* 10*s.*

Turning now to the oil pictures, it will be found that in the first gallery, always a good room for sales, ten works have found purchasers, the amount realised being 1,487*l.* 5*s.*, compared with 1,395*l.* 16*s.* last year. Chief among the pictures sold in the first gallery are the "City of Newcastle-on-Tyne," by Mr. Niels M. Lund (315*l.*); Mr. La Thangue's "Nightfall" (300*l.*); "Phyllis is my only Joy," by Mr. Seymour Lucas (250*l.*), and Mr. Sidney Cooper's "A Morning in Autumn" (250*l.*). In the second gallery the sales amount to 1,735*l.* 2*s.*, against 603*l.* 10*s.* in 1897. Here Mr. Melton Fisher has sold to the Chantrey trustees for 500*l.* his picture "In Realms of Fancy." Mr. Godward's "Nymph of the Chase" has gone for 250*l.*, Miss Jessie Macgregor's the "Room with the Secret Door" for 210*l.*, Mr. Logsdail's "Going to the Procession" for 175*l.*, and Madame Henriette Ronner's "Memories and Anticipations" for 150*l.*

So far the sales have shown an improvement instead of a depreciation when compared with those of last year, and it is not until the great third gallery is reached that the signs of falling-off become apparent. Here, however, the loss is a serious one. In 1897 the sales in the large room amounted to no less than 4,171*l.* 15*s.*, this year they are only 1,930*l.*, and the greater part of this is represented by the price of one picture, Mr. Frank Dicksee's "An Offering," which was disposed of for 1,200*l.* The other pictures sold in gallery three are "Charles II. at Whiteladies," by Mr. Ernest Crofts (400*l.*), the "Ash Grove," by Mr. G. D. Leslie (200*l.*), Mr. Ralph Peacock's "Ethel," which has been purchased by the Chantrey Trustees (105*l.*), and a small painting by Mr. Owen Dalziel, "A Rescue" (25*l.*)

In the fourth gallery the sales are considerably better than last year—1,289*l.* 7*s.*, compared with 989*l.* 12*s.* In this room Mr. Alfred Parsons's landscape, "The Mooters" (840*l.*) and Mr. C. E. Perugini's "Weary Waiting" (400*l.*) are the chief pictures sold. The sales in the fifth gallery show, on the other hand, a deplorable falling-off from the 1897 figures. Last year several important canvases in the fifth gallery found purchasers for a total sum of 1,762*l.* 10*s.*, but now only one picture is sold—only one, that is to say, of those priced for sale in the catalogue. This is "The Magic Mantle" (100*l.*), by Miss I. L. Gloag. The returns from the sixth gallery are more depressing still. Five pictures have been sold, it is true, but they realised between them only 78*l.* 3*s.*, while last year's sales amounted to 1,933*l.* In gallery seven, where Miss Margaret Dicksee's picture, "A Sacrifice of Vanities," has been disposed of for 250*l.*, the figures are better than those of 1897—497*l.* 10*s.*, against 254*l.* 15*s.*; but in gallery eight, where last year pictures to the value of 1,359*l.* 15*s.* were sold, the balance is once more on the wrong side. The sales this year in the eighth gallery amount only to 705*l.* 5*s.*, the highest price (400*l.*) having been given for Mr. Joseph Farquharson's "The Weary Waste of Snows."

This year at the Academy small pictures have sold much better than last. No fewer than forty of the 208 little canvases shown in the ninth gallery—a room which is always devoted to small pictures—have found buyers. The highest-priced picture sold in the ninth gallery is an interior by Miss Jessica Hayllar, which has been disposed of for 157*l.* 10*s.* The sum total of the sales in this room amounts to 951*l.* 8*s.*, compared with 826*l.* 16*s.* last year. In the tenth gallery, which is not usually a good room for sales, exhibitors have done very well this year. Nine pictures have found purchasers for a total sum of 1,788*l.* 5*s.*, compared with seven pictures and 903*l.* 15*s.* in 1897. In the tenth gallery the largest sums have been given for Mr. H. J. Draper's "The Lament for Icarus," bought by the Chantrey Trustees for 840*l.*; Mr. W. L. Wyllie's picture of "The Harbour Bar" (350*l.*); and Mr. Sidney Cooper's "On a Sunny Afternoon" (250*l.*). The sales in the eleventh gallery are also good, 840*l.* 8*s.*, against only 391*l.* 6*s.* last year. In this room, as in the last, the Chantrey Trustees have made a purchase, giving 500 guineas for Mr. Yeend King's "Milking Time."

In the sculpture galleries the sales, which were bad last year, show a further decline. Only seven of the works on sale in the Central Hall and Lecture Room have been disposed of, and two of these were sold for a guinea each, one for three guineas and one for eight guineas. Mr. Hamo Thornycroft is the only sculptor upon whom fortune has smiled at the Academy this year, his bronze statuette "The Bather" having been sold for 250*l.* Finally, in the little gallery devoted to works in black and white, seven drawings, at prices ranging from one to eight guineas, have been sold for a total sum of 30*l.* 15*s.*

It must, of course, be understood that the figures given

above refer only to the official sales at the Academy, and that a certain number of pictures, including some of the most important, are disposed of privately. The only pictures which have been dealt with are those which were sent to Burlington House priced for sale; but these naturally form the large majority of the exhibited works, for the Academy is incomparably the best selling gallery in England. Numbers of artists build their chief hopes on the chance of selling their works at the Academy, and to them the great falling-off in the sales is a matter of very serious import.

ART MUSEUMS.

THE select committee on the museums of the Science and Art Department have arrived at the following conclusions and recommendations :—

The collections would be more highly appreciated and rendered of greater value to the community if explanatory lectures were given. Such lectures have been delivered at Dublin and in Jermyn Street, and with encouraging results.

In forming a judgment as to purchases it must be remembered that there have been great changes of taste during the forty years which have elapsed since the museum was founded. There has also been a great extension of information, and the true value has been given to many objects respecting which little was formerly known. Mistakes have doubtless been made, but they have been unimportant compared with the magnitude of the collections. After withdrawing from circulation objects of no value there remains such an increase in the value of other objects purchased that the loss arising from those errors becomes of small account.

There are a number of duplicate prints; these might be disposed of as gifts to provincial museums and schools. The South Kensington authorities have recently taken a wise step in transferring to other public institutions objects which do not properly come within their own sphere. Thus the National Gallery has received several important Italian paintings by Perugino and the younger Bellini. They still belong to the Science and Art Department, but nobody could question the propriety of this transfer. So also the British Museum has taken over the custody of the collection of coins formerly shown at South Kensington. We are aware that the interrelation of our public museums and galleries involves issues of controversy as well as of importance. Our reference does not permit us to enter upon a discussion of this subject. We may, however, be allowed to indicate that the question is well worthy of detailed consideration by suggesting (*a*) the relations of Kew and Jermyn Street Museum respectively to the Natural History Museum; (*b*) of South Kensington to the British Museum; (*c*) of the three metropolitan picture galleries to the Chantry Bequest and South Kensington; (*d*) of the Public Record Office to the archive departments of various Government offices; (*e*) and, lastly, the general relation of our national collections to those maintained by municipal bodies. The Art Library at South Kensington has a large collection of "national portraits," engravings, prints and so forth. Some of these would be more appropriate to the National Portrait Gallery, whither they should be transferred. It has been pointed out that there would be no objection to this transfer provided that those engravings which were suitable to an art library as illustrating costume, lace, armour or styles of engraving were retained at South Kensington. The others, being of purely historical interest, should be handed over to the trustees of the National Portrait Gallery.

With a view to the efficient and economical management of the museums in London, to say nothing of other educational advantages not within the order of reference, your committee deem it of paramount importance that there be an Education Minister of Cabinet rank having a seat in the Legislature aided by a Parliamentary secretary.

They recommend that the Secretary for the Science and Art Department, like the Secretary of the Education Department, have his office at Whitehall.

That there be advisers or visitors who would assist the Department by suggestions or information in matters affecting the museums, but would not lessen the responsibility to Parliament of the Parliamentary chiefs. Such a system exists in Dublin, and works well. The Board of Admiralty and the Indian Council render valuable assistance to the great officers of State, but do not shelter them from responsibility.

That, with a view to facilitating communications between the Parliamentary heads and the principal officers of the museum, one at least of the former visit the museum weekly or more frequently and confer with such members of the staff as the state of current business renders it desirable that he should consult.

That a wide discretion as to the duties of the staff continue to be vested in the Parliamentary heads and those immediately responsible to them, it being impossible to foresee what modifications of any given system may be called for by new circumstances. Your committee desire, however, to state their opinion that (1) larger discretion as to purchases ought to rest with the director of the Art Museum as well as with the director of the Science Museum, and (2) scientific objects be placed on the west side of Exhibition Road exclusively, the Art Museum, the Art Library, provision for art teaching, and for loans for art objects being placed on the east side exclusively. The Royal College of Science may remain for a time, if the subjects taught be such as not to cause the discharge of gases injurious to art objects or danger of fire from inflammable and explosive substances. The scientific world have expressed their views in support of this arrangement of the buildings in a memorial presented to the Prime Minister by the Royal Society. Members of the Royal Academy and other artists have made like representations. The Department of Science and Art has not submitted to the committee any evidence in an opposite sense, but members of their staff have given testimony in favour of the views expressed by your committee.

That in accordance with the same report the Geological Museum in Jermyn Street be not occupied as now, but that the collections there exhibited be removed to the west side of Exhibition Road as a science collection. Care should be taken that all the special characteristics of the Jermyn Street Museum be preserved, and that the collection when removed be so served that officers be as far as practicable assigned to different divisions in the art museum in order that they may become accomplished experts.

That the director of the Science Museum should possess scientific attainments, and that the director of the Art Museum have like qualifications as regards art.

That the higher staff at the South Kensington Museum, being in point of numbers inadequate to the due discharge of the duties imposed upon it, ought to be increased.

That, having regard to the annually increasing demand made by local museums and schools of art on the South Kensington collection for circulation, it is desirable that the Parliamentary grant for purchases be increased.

That admission to all the museums be always free.

That in accordance with their first report of the present year there be in the Science Museum and Science Library, provision for science instruction and for loans for same purposes as at present, with the exception that the artistic pottery should be placed in the art museum. The relations between the Geological Survey and the Geological Museum are such that the offices of the former must necessarily be in close proximity to the Geological Museum.

That provision be made for the residence of some of the principal officials in the immediate neighbourhood of the museum within which they are employed.

That negotiations be carried forward with a view to transferring to some local authority the site and structure of the Bethnal Green Museum, the Dixon collection of pictures, and any other objects specially dedicated by donors under their wills or otherwise. They are of opinion that meanwhile more changes in the objects exhibited might be made with advantage to the district. The committee, however, call attention to the evidence of the difficulty, if not impossibility, of obtaining subscriptions from the ground landlords and industrial capitalists. They are of opinion that further gifts of public money should only be given to meet corresponding contributions from local sources, by way either of rates or of private subscriptions.

TESSERÆ.

Effects of National Taste.

UNLESS the national taste is improved we can hardly hope that the arts will rise to any great degree of perfection. The instructors of the public mind will mislead instead of guide those whom they profess to teach, and will be seduced and led astray by that meretricious ornament and false taste against which they ought to warn others, and from which they should divert them to the admiration of real excellence. It cannot be doubted, however, that there is a considerable love for art diffused throughout the nation, especially among the highly-educated classes, who evince their pleasure in the contemplation of the masterpieces of art, whether in painting, sculpture or architecture, by their thronging to the galleries and collections on the Continent as well as to those in our own country, and by the care and expense which they scruple not to incur in making and enriching their own collections. But even among these persons a very limited knowledge only is possessed of the real principles and objects of these last-mentioned arts, although with poetry and music they are tolerably well acquainted. Indeed, from the want of a proper study of the art of painting, and sculpture more especially, many men of talent know nothing of their capabilities and objects, and such persons form their ideas, or rather inadequate notions of them, from certain paltry performances which they have been in the habit of admiring. It is only when their capacities are known fully to persons of genius and cultivation, and are made a

branch of general study, that their real importance will be acknowledged, and that the patronage of the great will be extensively afforded to them. In the study of works of art of high intellectual merit, although we perceive not their excellence at first, by degrees it becomes developed to our minds. As we improve in our taste their value becomes apparent to us. The very cultivation which they serve to afford qualifies us to estimate their worth. It was not any deficiency in these works, but our own deficiency, which prevented us from doing justice to them originally. Our true and ample appreciation of them is the surest proof of our own advancement.

Giorgio Vasari.

Of modern writers on art Vasari leads the van; theorist, artist, critic and biographer in one. The history of modern art owes, no doubt, much to Vasari; he leads us from its cradle to its maturity with the anxious diligence of a nurse, but he likewise has her derelictions; far more loquacious than ample, and less discriminating of styles than eager to accumulate descriptions, he is at an early period exhausted by the superlatives lavished on inferior claims, and forced into frigid rhapsodies and astrologic nonsense to do justice to the greater. He swears by the divinity of Michel Angelo. He tells us that he copied every figure of the Cappella Sistina and the Stanze of Raphael, yet his memory was either so treacherous, or his rapidity in writing so inconsiderate, that his account of both is a mere heap of errors and unpardonable confusion; and one might almost fancy that he had never entered the Vatican. Of Correggio he leaves us less informed than of Apelles. Even Bottari, the learned editor of his work, his countryman and advocate against the complaints of Agostino Carracci and Federigo Zucchero, though ever ready to fight his battles, is at a loss to account for his mistakes. He has been called the Herodotus of art, and if the simplicity of his narrative and the desire of heaping anecdote on anecdote entitle him in some degree to that appellation, we ought not to forget that the information of every day adds something to the authenticity of the Greek historian, whilst every day furnishes matter to question the credibility of the Tuscan.

Royal Patronage in England.

From the age of Henry VIII. to our own Britain never ceased pouring its caravans of noble and wealthy pilgrims over Italy, Greece and Ionia, to pay their devotions at the shrines of virtù and taste. Not content with adoring the obscure idols, they have ransacked their temples, and none returned without some share in the spoil. In plaster or in marble, on canvas or in gems, the arts of Greece and Italy were transported to England; and what Petronius said of Rome, that it was easier to meet there with a god than with a man, might be said of London. Without inquiring into the permanent and accidental causes of the inefficacy of these efforts with regard to public taste and support of art, it is observable that whilst Francis I. was busied not to aggregate a mass of painted and chiselled treasures merely to gratify his own vanity, and brood over them with sterile avarice, but to scatter the seeds of taste over France by calling, employing, enriching Andrea del Sarto, Rustici, Rosso, Primaticcio, Cellini, Niccolo; in England, Holbein and Torregiano under Henry, and Federigo Zucchero under Elizabeth, were condemned to Gothic work and portrait painting. Charles, indeed, called Rubens and his scholars to provoke the latent English spark, but the effect was intercepted by his destiny. His son, in possession of the cartoons of Raphael, and with the magnificence of Whitehall before his eyes, suffered Verio to contaminate the walls of his palaces, or degraded Lely to paint the Cymons and Iphigenias of his Court; whilst the manner of Kneller swept completely what yet might be left of taste under his successors.

Winckelmann and Mengs.

About the middle of the last century the German critics established at Rome began to claim the exclusive privilege of teaching the art, and to form a complete system of antique style. The verdicts of Mengs and Winckelmann became the oracles of antiquaries, dilettanti and artists from the Pyrenees to the utmost north of Europe, have been detailed, and are not without their influence here. Winckelmann was the parasite of the fragments that fell from the conversation or the tablets of Mengs, a deep scholar, and better fitted to comment a classic than to give lessons on art and style: he reasoned himself into frigid reveries and Platonic dreams on beauty. As far as the taste or the instructions of his tutor directed him, he is right whenever they are, and between his own learning and the tuition of the other his history of art delivers a specious system and a prodigious number of useful observations. He has not, however, in his regulation of epochs discriminated styles and masters with the precision, attention and acumen which, from the advantages of his situation and habits, might have been expected, and disappoints us as often by meagreness, neglect and confusion, as he offends by laboured and inflated rhapsodies on the most celebrated monuments of art. To him Germany owes the shackles of her artists and the narrow limits of their aim; from him they have learnt to substitute the means for the end, and, by a hopeless chase after what they call beauty, to lose what alone can make beauty interesting—expression and mind. The works of Mengs himself are, no doubt, full of the most useful information, deep observation and often consummate criticism. He has traced and distinguished the principles of the moderns from those of the ancients, and in his comparative view of the design, colour, composition and expression of Raphael, Correggio and Titian, with luminous perspicuity and deep precision pointed out the prerogative or inferiority of each. As an artist he is an instance of what perseverance, study, experience and encouragement can achieve to supply the place of genius.

Greek Masonry.

What must be observed in the edifices of Greece is the high finish of all the parts. In them the object, which is not intended to be seen, is wrought with as much care as the exterior composition. The junctures of the blocks which form the columns of the Parthenon are so perfect as to require the greatest attention to discover them, and they leave a mark no thicker than the finest thread. In order to attain this extraordinary perfection, the marble was first reduced to its proper shape by a chisel. Afterwards the two pieces were rubbed one upon the other, and sand and water thrown upon the centre of friction. The courses, by means of this practice, were placed with incredible precision, and this precision in the shafts of the columns was determined by a square pivot of olive wood. The roses, the plinths, the mouldings, the astragals, all the details of the edifice, exhibit the same perfection. The lines of the capitals and the fluting of the columns of the Parthenon are so sharp, that you would be tempted to suppose that the entire column has passed through a lathe. No turners' work in ivory can be more delicate than the Ionic capitals of the Erechtheum; and the Caryatides of the Pandroseum are perfect models.

Province of Painting.

Though the painter borrows his subject, he considers his art as not subservient to any other. His business is something more than assisting the historian with explanatory figures; as soon as he takes it into his hands he adds, retrenches, transposes and moulds it anew till it is made fit for his own art; he avails himself of the privileges allowed to poets and painters, and dares everything to accomplish his end, by means correspondent to that end—to impress the spectator with the same interest at the sight of his representation, as the poet has contrived to impress on the reader by his description; the end is the same in both cases, though the means are and must be different. Ideas intended to be conveyed to the mind by one sense cannot always with equal success be conveyed by another. Even the historian takes great liberties with facts in order to interest his readers, and makes his narration more delightful; much greater right has the painter to do this, who, though his work is called history-painting, gives in reality a poetical representation of events.

GENERAL.

Mr. Ernest Crofts, R.A., has been appointed keeper of the Royal Academy in succession to the late Philip H. Calderon.

The Foundation-stone of an asylum for the county borough of West Ham was laid on Wednesday by the Mayor of West Ham, Alderman Ivey, at Chadwell Heath, Essex. The buildings, which cover more than 10 acres, with 90 acres of surrounding land, will accommodate 800 patients and staff. The total cost, when finished, will be about 300,000*l.* The architect is Mr. Lewis Angell.

The Monmouthshire County Council have appointed a committee to take such action as they may think necessary with a view to securing Raglan Castle and Tintern Abbey for the public. These properties are part of the Duke of Beaufort's estates in Monmouthshire which his Grace transferred to the Marquis of Worcester, and are now in the market with the rest of the estates.

The Mansion of Wester Livilands, near Stirling, is about to be demolished, and a new house erected on the site. According to tradition, General Monk resided in the mansion during the siege of Stirling Castle. Six painted panels of the Sibyls were found, of which the origin is uncertain.

The Bournemouth Town Council on Wednesday accepted tenders for carrying out a scheme for lighting the lower pleasure gardens, pier, and winter gardens by electricity, and it was decided to hold a special meeting to consider the desirability of applying for a provisional order empowering the Corporation to adopt a scheme for lighting the town generally by electricity.

THE
Architect and Contract Reporter.

IMPORTANT NOTICE.

WORKMEN'S COMPENSATION ACT.

In view of the many difficulties which are certain to arise in connection with the law, practice rules and procedure under the above Act, we have added to our staff A VERY EMINENT BARRISTER, who has made the subject a special study, and will be glad to answer in the columns of this paper any questions relating to the complicated matters arising from the provisions of this difficult Act. Our LEGAL ADVISER will further answer any legal question that may be of interest to our readers. All letters must be addressed "LEGAL ADVISER," Office of "The Architect," 175 Strand, London, W.C.

EDITORIAL NOTICES.

The authors of signed articles and papers read in public must necessarily be held responsible for their contents.

No communication can be inserted unless authenticated by the name and address of the writer—not in every case for publication, but as a guarantee of good faith.

Correspondents are requested to make their communications as brief as possible. The space we can devote to Correspondence will not usually permit our inserting lengthy communications.

TENDERS, ETC.

*** *As great disappointment is frequently expressed at the non-appearance of Contracts Open, Tenders, &c., it is particularly requested that information of this description be forwarded to the Office, 175 Strand, London, W.C., not later than* 2 P.M. *on Thursdays.*

NEW READING CASE.

To Librarians of the Public Libraries and Reading-rooms.—A new handsome Reading Case can be supplied at a nominal charge of 2s., by post 2s. 6d., on early application to the Publisher, 175 Strand, W.C.

For Advertisement Scale, see page xv.

BUILDING AND BUILDERS.

In carrying out the programme of Her Majesty's Government additional buildings are required at Lancaster and Bury. These are to be erected immediately, and the contracts have been given to Mr. Samuel Warburton, of Miles Platting.

A freehold site in Nightingale Lane, Clapham Common, has been secured for the new premises of the Jews' Deaf and Dumb Home, whose building in Walmer Road, Notting Hill, has been condemned by the inspector of the Education Department as inadequate.

The erection of a cottage hospital for Morecambe will shortly be proceeded with. At a meeting of the diamond jubilee committee, held in the Albert Hall, several tenders were recommended for acceptance by the building committee, these amounting in all to 1,900*l.* 14*s.* To this sum, however, the chairman explained, must be added the cost of the furnishing, which would bring the total cost to 2,500*l.*

A new parish has been formed in Llandaff diocese. The parishes of St. Woollos and St. Mark, Newport, Monmouthshire, have yielded a portion within their area to form a new district to be known as St. John the Baptist, and a church is in course of erection.

The Bristol Town Council have resolved to promote a Bill for spending 350,000*l.* on dock extension works at Portishead, in order to meet urgent requirements of the Elder Dempster, Canadian and American traffic and other Transatlantic trade.

Plans for the reconstruction of the interior of South Queensferry parish church, Linlithgowshire, prepared by Mr. Chalmers, architect, have been approved of by the Kirk Session and Presbytery. The cost will be 400*l.*

A new school is about to be erected at Thornhill, about half way between Partick and Whiteinch, on a slope overlooking the Clyde. The proposed buildings will form a square, to be surrounded by four new streets which have not yet been finished. Accommodation will be provided for 1,332 scholars, and the estimated cost of the entire buildings is 18,000*l.*

The plans for an archbishop's residence at Canterbury have now been definitely settled by the Ecclesiastical Commissioners. Additions are to be made to the house that was in former times the archbishop's palace, and some houses in Palace Street are to be pulled down for the purpose of allowing of the extension. The scheme is a large one, and when carried out will greatly add to the architectural features of the cathedral precincts.

The site of the new lunatic asylum for the county borough of West Ham, the foundation stone of which was laid on the 3rd inst., is at Chadwell Heath, Essex, and the building is designed for the reception of 800 patients in various blocks, distributed in the following proportion:—Males: Sick and infirm, 88; acute, 70; epileptic, 80; chronic, 112. Total, 350. Females: Sick and infirm, 112; acute, 90; epileptic, 98; chronic, 150. Total, 450. The administration block is placed centrally, the front portion being occupied on the ground-floor by the chief medical officer's, steward's, and clerk's offices, board room, dispensary, library, &c., the museum and laboratories and assistant medical officer's rooms being on the first floor. At the back are the waiting-room, matron's apartments, recreation hall, rooms for male and female attendants, kitchen, bakery, general stores, laundry, boiler, engine-house, workshops, &c. The main buildings will be two storeys in height, and will occupy an area of about 10 acres, with 90 acres of surrounding land. The foundations have been put in by Messrs. Gregar & Son, of Stratford, at a cost of about 16,000*l.* Messrs. Leslie & Co., of Kensington, have the contract for the superstructure—210,000*l.* In addition to the main buildings there will be a medical officer's residence, also steward's, chief attendant's and married attendants' houses, isolation block, mortuary, lodges, and a chapel to accommodate 550 adults. The total cost when finished will be about 300,000*l.* The architect is Mr. Lewis Angell, the borough engineer of West Ham.

TRADE NOTES.

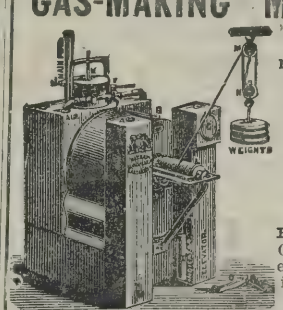
We understand that Messrs. Francis Morton & Co., Limited, of Hamilton Ironworks, Garston, are now in a position, as will be seen by our advertising columns, to execute orders. The undertaking has been acquired by a strong syndicate of Liverpool and Manchester gentlemen, and the services of Mr. Malcolm Blair, who was for eighteen years in the engineering department of the Pearson & Knowles Coal and Iron Company, have been secured. In addition to the extensive fencing and galvanising works handed over by the old company, the directors are laying down the latest machinery for drilled girders and bridge work.

The new workhouse hospital, Birkenhead, is being warmed and ventilated by means of Shorland's patent Manchester stoves, with descending smoke flues, and patent Manchester grates.

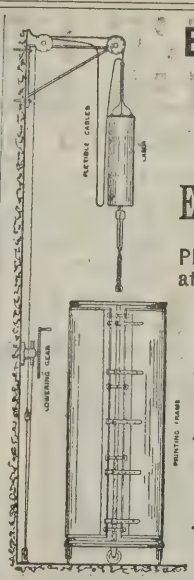
Billing's Burner Syndicate, Limited, of 180 Wardour Street, W., have supplied a large number of non-mantle incandescent gas light burners to light the Washington Music Hall, Battersea, S.W., which has recently undergone extensive alterations and redecoration.

Messrs. J. Carter, Sons & Co., of Salford, Manchester, have just purchased the business carried on by the late Mr. Edwin J. Oxley for the past seventy-eight years in Port Street, Manchester, as a mill and machine ironmonger and tool maker. Messrs. Carters have been established over forty years in the same class of business.

ELECTRIC NOTES.



The provisional orders granted to the Charing Cross and Strand Electricity Supply Corporation, Limited, for the supply of electric energy in that part of the St. Giles and Holborn districts lying to the south of New Oxford Street and High Holborn respectively have now been confirmed by Parliament, and only await the Royal assent to become law.



At the request of the Douglas Corporation, Professor Fleming presented a report with regard to the lighting of Douglas by electricity. It is in favour of such lighting by the Corporation, and he adduces the following grounds:—The profits accruing go to the ratepayers; monopolies of the kind should be in the ratepayers' hands; private consumers will be sure of fair treatment; the prospects for electric lighting in Douglas are encouraging, and the extra expenditure produces a superior illumination of which the public get the benefit. The estimated cost is about 30,000*l.*

The committee on electricity of Glasgow Town Council, in their sixth annual report, embracing the year ending May 31 last, state that the gross revenue amounts to 36,360*l.* 14*s.* 10*d.*, and the gross (or working) expenditure to 18,889*l.* 18*s.* 8*d.*, to which is added depreciation written off capital 8,945*l.* 1*s.* 9*d.*, the balance carried to profit and loss account being 8,524*l.* 14*s.* 4*d.* Out of this balance the committee had to meet interest on loans, 4,814*l.* 3*s.* 10*d.*, and sinking fund, 1,537*l.*, leaving a balance of 2,174*l.* 10*s.* 6*d.*, which has been placed to credit of reserve fund account.

An enquiry was held on Friday last, at the Salford Town Hall, into an application by the Salford Corporation for power to borrow 33,000*l.* for purposes of electric lighting. From the opening statement of the town clerk, and the evidence of the borough treasurer, the electrical engineer, and the chairman of the electricity committee of the Corporation, it appeared that 57,770*l.* has been already borrowed for the purposes of the electric installation, and that of the 33,000*l.* now sought to be borrowed, 10,000*l.* is required for land for a large new generating station at Strawberry Hill, Pendleton, 10,700*l.* for electrical mains, and 11,300*l.* for three battery sub-stations in the different districts of the borough, together with accumulators and the necessary machinery for charging and discharging the accumulators. In illustration of the urgent necessity for the provision of land for a new station, figures were given showing the great increase in the demand for the current. In the quarter ended in June 1897, the amount of current sold was 11,513 units, in the quarter ended September 1897 it was 16,234 units, in the quarter ended December 1897 it was 67,876 units, in the quarter ended March 1898 it was 89,898 units, and during the quarter ended June last it was 43,944 units, or getting on for four times the quantity sold in the corresponding quarter of last year. The demand was still increasing, and if one of the battery sub-stations was not completed by the coming winter the electricity committee would be in a fix. The witnesses said they expected to have in the coming winter new customers for 20,000 8-candle power lamps; applications had been received for motive power equal to about 2,000 horse-power, and motive power equal to about 6,000 horse-power would be required to drive the tramcars by electricity. The 10,000*l.* for the land it is proposed to borrow for 50 years, and the remainder of the sum for as long a period as the Local Government Board will allow.

VARIETIES.

On Monday a new board school was opened at Brynsiencyn, Anglesey, by the Hon. W. Irby, in the unavoidable absence of Lord Boston, who gave the site of the building.

Designs for the new railway station to be erected at Stockholm will be received up to Wednesday, 31st inst., at the offices of the Consulate, 27 Great Winchester Street.

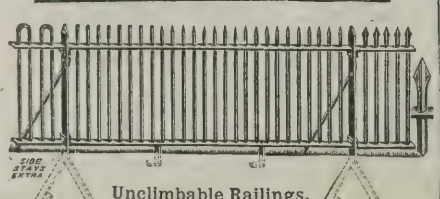
The new chapel which has been erected at Mar Lodge was consecrated on Sunday last in the presence of the Duke and Duchess of Fife. The chapel, which is of Norman architecture, is situated at the back of the mansion, is beautifully designed both internally and externally, and is admirably equipped in every way.

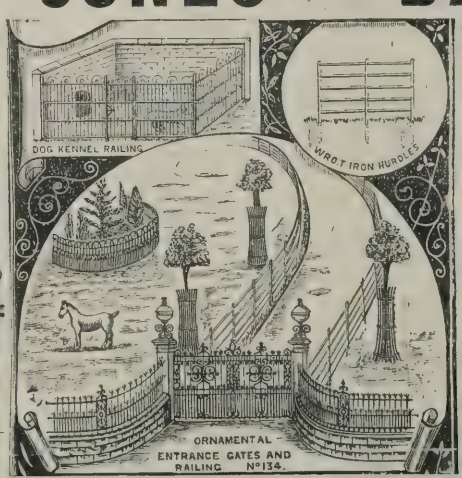
The sixth annual Laundry Exhibition, which will be held at the Royal Agricultural Hall, Islington, from Monday, August 22, to Saturday, September 3, will contain a large number of novelties, and will show a distinct advance in laundry engineering. There will be a beautiful display of finished linen.

Within a brief period a new town has sprung into existence at the south end of Temple, near Kilpatrick. On land which was purely agricultural some eight or ten years ago there now stands a village of nearly 3,000 inhabitants, and when the extensive building operations at present going on in all parts of this district are completed, it is expected the number will be raised to over 5,000. The valuation of the parish in 1895 was 103,000*l.*; at present it is 127,000*l.*—an increase of 24,000*l.*

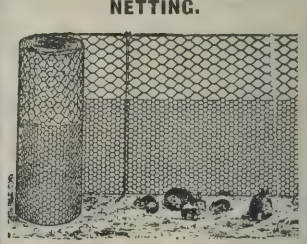
By the opening of the new and commodious harbour at Cologne an important addition has been made to the works undertaken for the advancement of the German water transit. The ancient fortifications proved for a long time a serious obstacle to any material extension of the harbour accommodation, and it was not till the former had vanished that the contemplated extension could be taken in hand in earnest. The bank of the Rhine has been regulated and turned to account for a distance of over 7 miles.

The City Corporation has decided to expend 2,500*l.* in carrying out certain alterations at the Basinghall Street entrance to Guildhall. These have become necessary through the demolition of the offices of the Chamberlain and the Weights and Measures Department and the erection of the new Public Health offices. A permanent entrance will be made from Basinghall Street, starting from the library and running northward to the new block of offices. This will form a public approach to the strangers' gallery of the Council Chamber and the eastern portion of the Guildhall and its committee-rooms. The entrance will be fitted with gate piers of wrought iron, and the footways and carriageways will be paved with asphalte. The opportunity will be taken to complete two buttresses and to add a new window to the Council Chamber, thus finishing the façade. A connection will also be made between the library and the Common Council Chamber for use on ceremonial occasions.





The Barton-on-Humber Waterworks were officially opened last week. The original works were built in 1888. The works consist of boiler, engine, and filtering houses, manager's house, and storage tank, capable of holding 120,000 gallons. The well is 120 feet deep, with a bore 25 feet deeper. There is a set of double pumps, capable of raising 23,000 gallons of water per hour.



At the annual meeting of the Royal Botanic Society, to be held in the Gardens on the 10th instant, at 1 P.M., Mr. J. S. Rubinstein will recommend that the present system of electing members of the Council, whereby they are practically elected and re-elected year after year by the Council itself, should be brought to an end; and further, that the scientific and administrative branches of the Society's work should be divided, and that each branch should be supervised by a competent manager. He will also propose (1) the establishment of classes for the study of botany to be open to all students; (2) the reorganisation of the refreshment department, and the obtaining of a license for the restaurant newly built in the Gardens; and (3) the erection of a large floral hall to serve as a winter garden, and wherein exhibitions, flower shows, receptions and musical promenades can be held in all seasons and in any weather, architects being invited to send in plans in competition.

NON-INFLAMMABLE WOOD.

Upwards of a year ago—in our issue of May 14, 1897, to be exact—we gave a description of the successful demonstration by the British Non-Flammable Wood Company of the fireproof qualities of their prepared wood. These qualities received abundant recognition here as they had previously done in America—whence the invention comes—and a demand for the prepared wood has arisen, large orders having been given by

VOLUME LIX. OF THE ARCHITECT.
Handsomely bound in Cloth, Gilt Lettered. Price 12s. 6d.
OFFICE 175 STRAND, LONDON, W.

(among others) the British Admiralty. To meet the demand the company found it necessary to erect extensive works. These having been completed were formally inaugurated on the 28th ult., and as they are the first of the kind erected in England and possess some features of novelty, a description will not be without interest.

The site of the works, situate at Wandsworth Bridge, Fulham, consists of an area of nearly 3½ acres on the riverside, and includes a wharf and river wall 100 yards in length, as well as ample stacking accommodation. The works comprise a cylinder-house, a boiler-house, drying-room, chemical store-room and offices, all of which are included in the one building. The cylinder-house is 125 feet long and 48 feet broad, and contains the three treating cylinders, the largest of which is 105 feet long and 7 feet in diameter, and is capable of holding a charge at one time of about 20,000 feet of timber board measure.

Above the cylinders are the large feed tanks, each having a capacity of 24,000 gallons. These tanks are in connection with the cylinders, and hold the fireproofing solution, which, before being run into them, is prepared in a special mixing tank in the boiler-house. A point of interest in connection with these cylinders is the doors or lids. Some idea of the pressure on these doors may be gathered from the fact that the internal pressure at times is between 200 and 300 lbs. per square inch, and the doors have an area of nearly 6,000 square inches. It is necessary, therefore, that some means be adopted which, while rendering the door water tight and pressure proof, will not cause too long a delay in opening and closing it. These requirements have been fully met. The doors, although weighing 7 tons, can be operated in a few seconds by two men working an ingenious system of radial steel bolts. The boiler-house, which is 42 feet square, contains the boilers, which are of the latest pattern steel Cornish boiler of 70 horse-power each. These boilers supply the necessary heat to the cylinders, and the steam required to work the pumps, drying fans and other machinery. The mixing tank for mixing the fireproofing solution is also in the boiler-house.

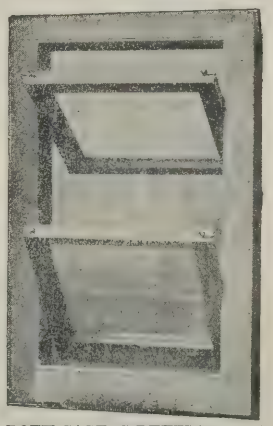
Since the wood by treatment is saturated to the heart, special drying capacities are required. The company's drying-room is of the latest design, and is 82 feet long by 40 feet wide, fitted with the most modern drying machinery specially adapted for the work required. It has a capacity for nearly 300,000 feet of timber, which can be thoroughly and equally dried in from twenty to forty days according to the thickness.

In the chemical storeroom are stored the chemicals required to manufacture the fireproofing solution. The room is 53 feet long and 42 feet wide, and will hold 200 tons of the chemicals required, which are specially manufactured for the company's use.

The offices include the test-room, in which the chemicals and solution are tested for strength and impurities.

In connection with the building is the traverse table which works on rollers in a traversing pit, and is a convenient method for conducting the cars loaded with wood from the timber yard to the cylinder-house, and from the cylinder-house to the drying-room; and, lastly, from the drying-room to the storehouse.

The ground adjoining the buildings is laid out with lines of rails, on which the cars or trolleys carrying the wood are easily conveyed to all parts of the works or grounds. Owing to the weight of a train of cars loaded with saturated wood it is necessary to employ mechanical power to move them. To effect this a system of sheaves has been inaugurated, around which travels a steel wire rope operated by a steam winch. By this means the cars are moved easily and safely, enabling timber to be taken either from the river or from the road, and discharged either into barges or into waggons, or if necessary into specially constructed storehouses to await despatch.



"SCAGLIOL" BUILDING SLABS.

WE were invited last week by the London Portland Cement Company, Limited, to visit their extensive works at Northfleet in order to witness a practical demonstration of the excellent fireproof qualities of their new "Scagliol" building slabs, and we were interested and gratified in watching the behaviour of the material throughout the severe ordeal to which it was subjected, and from which it is not too much to say it emerged triumphant.

A pavilion, measuring some 8 feet by 12 feet, built entirely of "Scagliol" in slabs 4½ inches thick, and divided in the centre by a partition 3 inches thick, was filled on the one side of the partition with wood, shavings, &c., saturated with petroleum and ignited. The "Scagliol" chimney of the building insured an ample draught, and the pyrometer within the building soon registered 1,600 deg., a height which has, we are informed, been considerably exceeded on some other occasions; but notwithstanding this great heat and the playing of the flames no one side of the partition against which they were drawn by

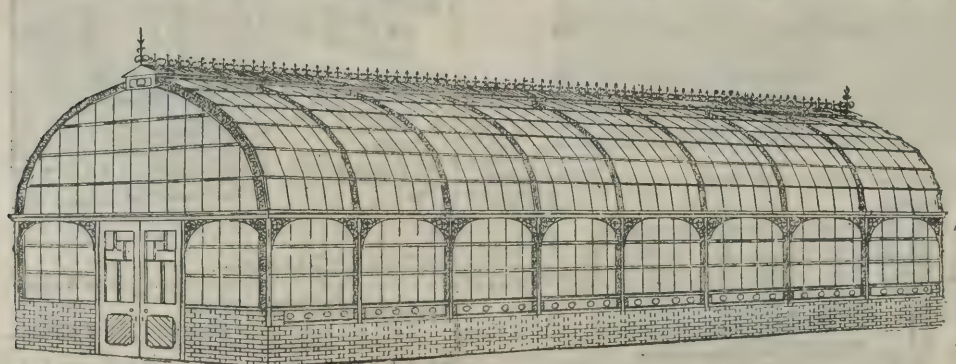
the action of the chimney, a thermometer inserted in the plaster of the other side registered under 80 deg. until water was thrown on the burning mass, when the temperature at once rose to 160 deg., which was the maximum heat obtained, and it is needless to say that neither some paper which was pasted on the wall nor a muslin curtain suspended against it was in the slightest degree affected. The fire was allowed to burn fiercely for 30 minutes, and on its extinction the building was found to be in every respect intact, while a specially constructed register indicated that the total expansion occasioned by the heat had not exceeded one-eighth of an inch.

In view of this satisfactory test of its fire-resisting capabilities, a brief description of "Scagliol" will no doubt be acceptable to our readers, and for this we cannot do better than make the following extract from the pamphlet issued by the manufacturers :—

"Scagliol is a mixture of plaster of Paris, slaked lime and other ingredients, subjected to a complex chemical treatment, to which sand, coal ash, or other suitable material is afterwards added. For mortaring purposes the dry scagliol 'powder' is mixed with lime-water and used liquid. Scagliol is used for making wall slabs, ceiling slabs, ceilings, chimneys. The most important articles made are the patented wall slabs invented in 1893. Walls made of these slabs are extraordinarily stable, fireproof and light, and will receive preference over thicker and bulkier walls where no great supporting strength is required. Owing to their light weight, scagliol walls may be erected where brick walls would weigh too heavily on the supports. Both wall and ceiling slabs are non-conductors of sound (an extremely important point in the building of flats), and they also afford protection against atmospheric changes of temperature. Their compactness also effectually excludes vermin, and is an absolute preventive of mould, fungus and dry-rot, as there is no vegetable matter in the slabs, the ingredients of which, as already stated, are solely mineral powder and burnt-out coal-ash or the like. In building, the slabs are set up lengthways in single horizontal rows. The joints between them are smeared over on the outside with scagliol mortar (which dries in a few seconds), the superfluous mortar being scraped off with a trowel. Very liquid mortar is next poured into the tube formed between each pair of slabs by the side-grooves, and running downwards it fills in turn the bottom grooves, the grooves and holes at the sides, and finally wells up to the top of the tube, showing that the mortaring is complete, and cementing the whole wall solidly together. Owing to the perfect smoothness and dryness of scagliol walls, they may be papered a few hours after erection, as no plastering at all is required, whereas an ordinary plastered brick wall, which takes a day to erect, would not be fit for papering until ten days or a fortnight after being built. Walls which are to be painted may be suitably prepared in a few hours by rapid plastering with scagliol powder and water. In a wall of 16 to 18 feet in length, the tie of one slab to another is so great that if it has been carefully built the entire bottom row of slabs (with the exception of the two end ones) may be removed without rendering the wall unsafe."

WAGES IN THE METROPOLIS.



A COMMITTEE of the London School Board recently agreed to make the following recommendation to the Board :—"That where, in any well-defined and extended trades, evidence is furnished to the Board of a recognised rate of wages accepted between employers and employed, such rate of wages be filed in the head offices of the Board, and be inserted in the contracts in like manner to the schedule of wages inserted in the building contracts of the Board."

The committee have since endeavoured to ascertain what are the "well-defined and extended trades" which would be concerned in the running contracts specified in the above list; and in these cases to communicate with the respective trade unions and the associations of employers, where they exist, with a view to obtaining information as to the recognised rates of wages accepted between employers and employed in each case. For this purpose the committee have been in communication with the labour department of the Board of Trade, and have consulted the publications issued by them bearing on the subject, including a list of the trade unions in existence throughout the country. The Commissioner of the Board of Trade (Mr. Llewellyn Smith) has also forwarded to the chairman of the committee a manuscript list of all the associations of employers of labour.

The following statement contains the result of these inquiries :—

1. *Furniture.*—The recognised minimum standard rate of wages for carpenters and joiners is 10*d.* per hour, as given in the wages schedule inserted in building contracts. It appears, however, that some firms engage cabinet-makers to manufacture the furniture. Inquiries have, therefore, been made

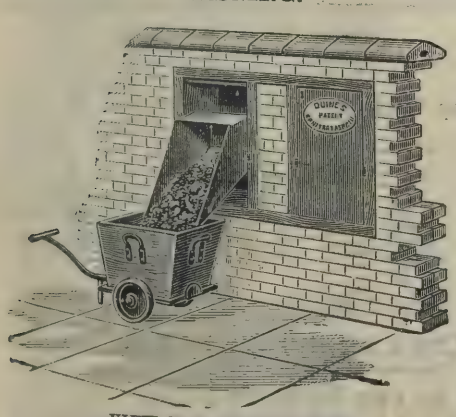
with regard to the minimum rate of wages for cabinet-makers with the following result:—The Alliance Cabinet Makers' Association (representing the workmen), which contains the largest number of members in this trade, states in its printed rules, dated April 1896, that the minimum wage is 9*d.* per hour, and for members working for firms undertaking shop fittings and interior cabinet fittings 9½*d.* per hour, the recognised hours of working being 52½ per week. The Cabinet Trades' Federation (representing the masters) states that "the rates of wages paid by members of the Cabinet Trades' Federation are from 8*d.* to 10*d.* per hour for efficient cabinet-makers, according to the class of work done," and adds that the working hours are 52½ per week. A copy of the statement of the Federation was forwarded to the Workmen's Association, who were asked if they had any observations to make upon it, but no reply has yet been received. The Bennet Furnishing Company, who hold the Board's contracts for dual desks, state that there is no standard rate of wages for cabinet-makers, but a minimum rate of 9*d.* per hour, or 9½*d.* per hour if working as shop fitters. Under the circumstances the committee are of opinion that a rate of 9*d.* per hour might be inserted in the schedule of wages which is now attached to all building contracts, and that this schedule (which also includes carpenters and joiners, painters, glaziers, labourers) should be inserted also in the contracts for woodwork furniture when fresh tenders are obtained.

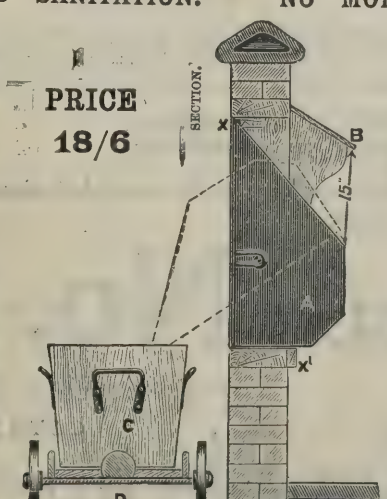
2. *Locks and Ironmongery.*—There does not appear to be any union in connection with this trade.

3. *Gas Mains and Fittings.*—The work in connection with the fixing of gas mains and fittings is done by smiths and fitters. The Board will recollect that when the schedule of wages was inserted in the building contracts in 1895, there was some discrepancy in the statement forwarded by the masters and men as to the rates of wages of smiths and fitters. The committee find that this discrepancy still exists, the Central Association of Master Builders of London stating that the rates of wages of smiths and fitters are from 9*d.* to 10*d.* per hour, and the Society of General Smiths, Fitters, Bellhangers and Whitesmiths (representing the men) stating that the wages are for each of these trades 10*d.* per hour. The committee are unable to recommend that the trade of smiths and fitters should be inserted in the schedule, and they recommend that a letter be forwarded to the society stating that, so long as this discrepancy exists, the committee will remain under the same disability, but will be prepared to reconsider the matter so soon as a recognised rate shall have been agreed to between the employers and employed.

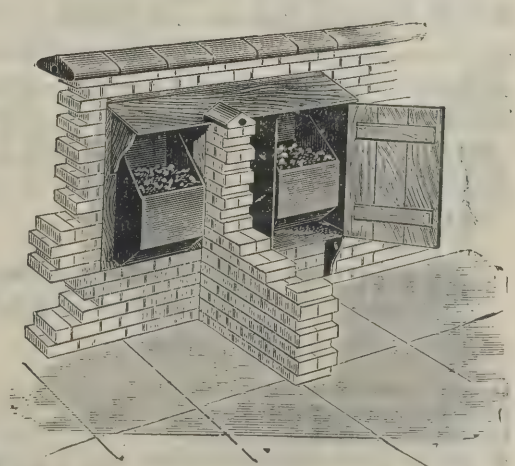
4. *Iron Founders.*—The Board are not largely concerned in this trade, as it would only apply to grate fronts, tubular boilers and radiators. The work is not done in London, and the British Iron Trade Association state that each district has its own rate of wages. This statement appears to be confirmed by the report of the Board of Trade.

5. *Brushmakers.*—The United Society of Brushmakers (representing the men) forward a schedule, consisting of several pages of piecework prices for the making of brushes, based on various methods of payment, from which it is to be assumed that there is no daily or weekly rates of wages recognised in the trade. This information is confirmed by Messrs. Kent & Sons on behalf of the Master Brushmakers' Association and also by the report of the Board of Trade.





6. *Tar-Paving.*—There does not appear to be any association of masters or men. Messrs. Hobman & Co. state that the wages paid are as follows:—Spreaders, 8*d.* per hour, or 6*s.* to 6*s.* 6*d.* per day; potmen, 6*d.* per hour, or 5*s.* per day for two turns of boiler 10 hours per day. Messrs. Constable & Co. state that the work is executed by a foreman and second layer at fixed weekly wages, *plus* expenses; that additional assistance is supplied by local labourers at rates payable in the respective districts, and that the men work 9½ hours on week days and 6½ hours on Saturdays. Mr. Neal states that the wages are 6*d.* per hour, the day consisting of 10 working hours. It will be remembered that the Board have already decided to treat the contracts for tar-paving and asphalte as building contracts, and as a result the schedule of wages attached to all building contracts will be inserted in these contracts also. The committee, however, do not see their way to recommend the extension of this schedule by the insertion of the wages for the special classes of workmen referred to above.



7. *Gas-meters, &c.*—The Amalgamated Society of Tin and Iron Plate and Gas-meter Makers forward a book of 40 pages of piecework prices, together with a list of six firms who, they state, have agreed to recognise these rates. None of these firms, however, are on the lists of contractors who supply ironmongery or gas-meters to the Board.

8. *Clocks.*—There is no association of masters or men in this trade, the work being mostly done as piecework, and paid for according to the quality of the work.

9. *Chairs.*—These articles are made in High Wycombe, Bucks, payment being made by piecework.

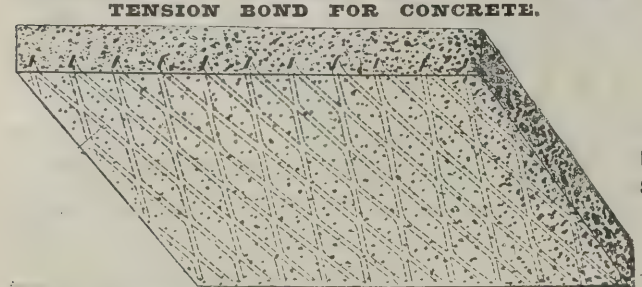
THE BIRMINGHAM SANITARY CONGRESS.

The local general committee appointed to make arrangements for the forthcoming visit of the Sanitary Institute to Birmingham met on the 21st ult. The Lord Mayor (Councillor Beale) presided. He said that would probably be the last opportunity which the committee would have of meeting, and he thought the public should know that the arrangements for the forthcoming congress were well forward. They might with confidence, he thought, look forward to a complete meeting in September. Over one thousand delegates had been appointed to attend by the different organisations, and if they added that number to those who are locally interested, they might be sure there would be large audiences. He was glad to know that there would be a most interesting collection of papers.

The officers, in their report, stated that the date fixed for the Sanitary Institute Congress is from Tuesday, September 27, to Saturday, October 1, inclusive. The inaugural address of the president will be delivered on Tuesday afternoon, September 27, and the conferences will be held in Mason University College on Wednesday, the 28th. The mornings of Thursday, the 29th, and Friday, the 30th, will be devoted to the sectional meetings. The arrangements for the Congress are in a forward state. The preliminary programme is now ready for issue, and it is expected that the full programme of local arrangements will be issued early in September. Tickets of membership of the Congress will be ready for issue at an early date, and may be obtained at the local offices, which are situate in the council-house. Holders of Congress tickets will be entitled to attend all the conferences and meetings of sections, to join the excursions, to admission to the exhibition, and will receive invitations to the reception given by the Lord Mayor and to the garden party at the Edgbaston Botanical Gardens. The Lord Mayor and the president of the Congress (Sir J. Fayrer, Bart.) will, in accordance with practice, attend a public luncheon, which will be held on September 27 at the Grand Hotel. The list of subjects to be discussed is an exhaustive one, principal among them being:—"Facts, Fancies and Fallacies of Vital Statistics," by Dr. E. F. Willoughby; "Antiseptics in Food," by Dr. A. P. Luff; "Prevention of Tuberculosis in Regard to Meat and Milk Supply," by Dr. T. M. Legge; "Birmingham Water Scheme," by Mr. J. Mansergh; "Sanitary Defects in Rural Districts: Remedies," by Mr. G. H. Smith; "Deep-well Boring in Warwickshire," by Mr. J. E. Willcox; "Construction and Ventilation of House Drainage," by Dr. A. Bostock Hill; "Natural Purification of Sewage," by Dr. Kenwood and Mr. W. Butler; "The Flora of Sewage," by Professor Boyce; "Dwellings of the Working Classes," by Dr. J. F. J. Sykes; "Cleansing of Persons Act," by Mr. A. Wynter Blyth; "Bacteriological Diagnosis and Infectious Disease," by Dr. Washbourn; "Relation of Medical Officers of Health to Schools," by Dr. Manley; "Precautions Observed in the Ventilation of Sewers and Drains," by Mr. T. J. Moss-Flower; "Teaching of Sanitation in Elementary Schools," by Mr. E. Day; "Sanitary Knowledge for Working Women," by Mrs. Wakeford; "Village Nursing and Infectious Disease," by Miss Wood; "Slaughterhouses in which Continental and English Methods are Compared," by Councillor Parkes, M.P.; "The Removal of Insanitary Areas and the Management of Improvement Schemes under the Housing of the Working Classes Act," by Mr. Peter Addie.



The reception and hospitality sub-committee reported, with regard to the entertainment of distinguished visitors, that the President of the Congress will be the guest of the Lord Mayor. For the reception of the Congress the Lord Mayor has granted the free use of the Town Hall for the purposes of a reception-room. The building will be fitted with writing and reading tables, easy chairs and lounges. The Council of the Midland Institute have granted the use of the large lecture theatre on the afternoon of Tuesday, September 27, for the President's inaugural address, and on the evening of Friday, September 30, for the lecture to the Congress, which will be delivered by Dr. C. Chiles. The council of the Mason University College have also granted the use of rooms in the college for the meetings of conferences and sections.

The report was presented by Councillor Godlee, who moved its adoption.

The excursion sub-committee reported that the following excursions had been arranged:—Friday, September 30—(1) To Dudley Castle and caverns; (2) to Whitacre reservoirs and pumping-station; (3) to Saltley sewage farm. On Saturday, October 1, to Stratford-on-Avon, Warwick and Malvern. Through the kindness of the Earl of Dudley visitors would be received by his lordship's representative, and conducted to the Wren's Nest limestone caverns, which would be reached by boat and water subway. The caverns would be illuminated by limelight, and after inspecting them the party would proceed to Dudley Castle, where tea would be provided. The chairman of the water committee (Alderman Lawley Parker) had offered to

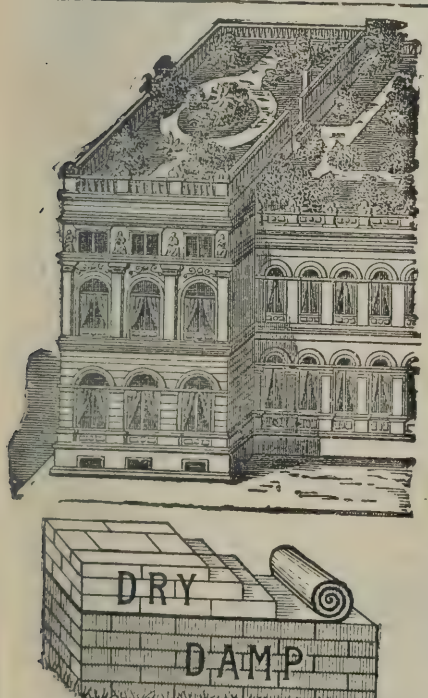
The YŌST TYPEWRITER CO., 50 Holborn Viaduct, E.C.

provide tea for the visitors to the Whitacre reservoirs and pumping-station, and Alderman Baker (chairman of the Tame and Rea District Drainage Board) had extended a similar invitation to the visitors to the sewage farm. The party travelling to Stratford-on-Avon and Warwick, after lunching at Stratford, would proceed to Warwick, where they would be received by the mayor of the city (Councillor Glover) and conducted over Warwick Castle. The authorities of Stratford had consented to waive the usual charges to the various places of interest, and the Earl of Warwick had also consented to forego the usual charge of admission to the castle. The visitors would be invited to tea by the Mayor of Warwick at the conclusion of their inspection. The Lord Mayor had consented to entertain members of the congress at a reception at the Council House on the evening of September 28, and the chairman and members of the health committee would invite the members to the garden party at Edgbaston on the afternoon of Thursday.

In their report of the arrangements of the exhibition the sub-committee state that they have rented Bingley Hall for a month—that being the only suitable building available. It will be necessary to board over the whole of the floor of the hall, to provide efficient electric lighting, gas for the stallholders, water and drainage, and to decorate the interior of the hall. It is estimated that the sum of 1,000*l.* allocated for these purposes will be sufficient to cover the total cost.



The expenses attendant upon the congress are estimated at 1,500*l.* This sum is made up as follows :—For rent and equipment of Bingley Hall for the purposes of the sanitary exhibition, 1,000*l.* ; for the general local expenses of the congress, 500*l.* A public appeal for guarantees to meet these expenses was issued to members of the local general committee, and widely in other directions in the city and neighbourhood, with the result that 2,005*l.* 5*s.* 6*d.* has been guaranteed by 396 persons.

WORKMEN'S COMPENSATION ACT.

A NEW departure of some importance has just been taken, says the *Times*, by four of the principal offices which undertake insurance against employers' liability under the Workmen's Compensation Act, which came into force on July 1, and under the Employers' Liability Act, 1880, and liability at common law. The Guardian and the Law Union and Crown, which have both for many years transacted life and fire insurance, and the Rock and Sun Life, which are very old life assurance companies, have joined forces for insurance against employers' liability of all kinds, including colliery, mine and quarry owners. This is an unusual course for companies to take in insurance matters, and therefore deserves special mention ; but probably other groups of companies will take similar measures. The more the provisions of the new Act are studied the more onerous the burdens imposed by it are seen to be, and it is found to bristle with difficulties and doubtful points from beginning to end. One feature of special importance is that the compensation that may be claimed under the Act involves in some cases periodical payments during the whole continuance of the life of an injured workman. This makes it essential for employers to satisfy themselves of the financial stability of any companies or schemes by means of which their liabilities are provided against. A company may be sound to-day, but some ten or fifteen years hence its position may be less favourable, and the annuities it has contracted to pay the workman on behalf of the employers may no longer be forthcoming. The same consideration applies with even greater force to combinations among employers, the permanence of which presents many difficulties. It is not easy to see how adequate safeguards can be introduced to prevent the breaking up of such combinations in the course of a few years. Some members of the combination may fail or discontinue business, or may be dissatisfied with the operation of the scheme as working unfairly towards the more careful employers. In such cases employers who had incurred responsibilities to workpeople might find themselves in a serious position.

For those employers, therefore, who place security and certainty in the front rank such a combination of wealthy and old-established companies as is mentioned above may prove attractive. Under the scheme they have adopted these four offices divide the responsibility incurred under the policies issued by any one of them, and so offer to the owners of collieries, mines and quarries their combined protection. An important feature of the scheme that is especially suitable to the risks incurred under the new Act is that employers will participate in the profit realised, and should the premiums charged exceed the cost of the insurance and a moderate profit to the offices the surplus will be returned to the policy-holders. After paying the claims and expenses of settlement, together with a fixed percentage of the premiums for expenses of management, 10 per cent. of the premiums will be taken as profit by the companies, 5 per cent. will be set aside to form

PATENT
VULCANITE ROOFING.

Since the introduction of the patent Vulcanite Roofing into this country it has been adopted by a great number of leading architects for Public and Private Buildings, Hotels, Schools, Hospitals, Theatres, Mills, Warehouses, Breweries, Shops, Villas, Dwelling-houses, &c.

The temperature of the rooms immediately beneath the roof is more even in winter and summer than under any other roof. When properly laid repairs are never required, and all roofs are guaranteed. The roof-surface can be used as a garden, or for any other purpose. The cost of construction is less than even for a slate or tiled roof.

SHEET ASPHALTE for DAMP-COURSE, WATERPROOFING VAULTS, BRIDGES, TUNNELS, &c., is manufactured ready for use in lengths of 40 feet, and any width up to 40 inches, being more convenient than the usual damp-course slabs, and saving laps. Price lower and quality much superior to any similar article in the market.

SHEET ASPHALTE for ROOFING SHEDS, LIGHT BUILDINGS, &c., and for SARKING under slates or tiles, manufactured in five different qualities and in rolls of 15 superficial yards. It is easily laid, very inexpensive, much superior to felt roofing, and requires no annual coating.

Full particulars, Catalogues, Detail Sketches, Estimates, re Vulcanite Roofing ; Samples, Prices, &c. re Sheet Asphalte, free.
THE PATENT VULCANITE ROOFING & ASPHALTE CO., LTD.,
28 VICTORIA STREET, WESTMINSTER, LONDON, S.W.
Inquiries from the North of England, Scotland, and Ireland, please address to Laganvale, Belfast.
Agents wanted in all districts where not yet represented for laying of Vulcanite Roofs and Sale of Sheet Asphalte.

a "catastrophe" fund, and the balance will be returned to the employers. This seems a perfectly adequate way of solving the difficulty of the rates of premium, about which so much controversy has raged. By the scheme of profit-sharing the rates, which by some people are said to be excessive, can be readily and equitably brought to fair proportions, should experience prove that the people who are likely to be the best informed on the question are wrong and that the rates now being quoted are too high.

The following scheme has been posted up at three collieries belonging to the Marquis of Bute. They are the Bute Merthyr, in the Rhondda Valley, and the Tower and Aberdare Merthyr, in the Aberdare Valley. The scheme has been approved by the Registrar of Friendly Societies, and will be carried out by Lord Bute for the benefit of every miner who is disposed to enter into it :—

Workmen's Compensation Act, 1897.

Scheme under the Workmen's Compensation Act proposed to be adopted at Lord Bute's collieries.

Contributions.—The employer, 5*d.* per week ; the workmen, 3*d.* per week.

Benefits :—

Accidental death :—

Workman leaving no dependent relative	£20	0	0
Workman leaving dependent relative :—			
Funeral allowance	5	0	0
Widow, per week	0	5	0
Each child under thirteen, per week	0	2	6

And the following additional benefits to Widows and children :—

1*l.* on birth of posthumous child.
2*l.* on child going off funds.
1*l.* on death of child.
15*l.* on remarriage if no child.
12*l.* 10*s.* on remarriage if one child.
10*l.* on remarriage if two children.
7*l.* 10*s.* on remarriage if three children.
5*l.* on remarriage if four children.
2*l.* 10*s.* on remarriage if five children.
1*l.* 5*s.* on remarriage if six children.
3*l.* funeral allowance on death of widow.

Non-fatal Accidents.—An allowance from the date of injury, and to continue throughout the first twenty-six weeks of disablement, at the rate of 10*s.* per week ; throughout the remaining period of disablement 8*s.* per week. For any disabled member in receipt of relief whose death does not result from the accident which placed him on the funds, 5*l.* funeral allowance.

Aged and Infirm Miners.—Upon the attainment of age sixty-five, and being unable to work through infirmity, an allowance of 5*s.* per week.

Notice.—Any workman is at liberty within fourteen days from the date hereof to send in writing to E. W. Brabrook, Esq., C.B., Chief Registrar of Friendly Societies, 28 Abingdon Street, London, S.W., any observations he may wish to make upon this scheme, and such observations will be considered by him at the expiration of that time.

Dated this 30th day of June, 1898.

PATENTS.

[*This List of Patents is compiled specially for this Journal by Mr. G. H. Rayner, of the firm of Rayner & Co., Consulting Patent Agents, 37 Chancery Lane, London, W.C. from whom all particulars and information relating to Patents may be had gratuitously.*]

Applications for Patents.

15901. John Pollock, for "An improved process for polishing wood, marble, metal and other substances, and machinery connected therewith."

15960. Elmer Ellsworth Van Wie and Joseph John Jacobs, for "Improvements in the construction of building tiles."

16076. Robert Robson Speris, for "Improvements in the construction of portable sectional buildings of wood and iron, or other composite materials."

16780. Beer, for "roofs and roofing."

19105. Maxted and McDermott, for "Brickmaking machines."

20980. Collier, for "Apparatus for pressing bricks, tiles and the like."

To Inventors.—Patents for Inventions, Trade-marks and Designs secured ; every assistance given to inventors. Specialists in Building matters. Information free.—Messrs. Rayner & Co., Patent Agents, 37 Chancery Lane, London, W.C.

THE WEEK.

Professor Georg Ebers, who died on Monday in his sixty-first year, did much to popularise the works of the ancient Egyptians. His large book on Egypt, which is so abundantly illustrated with German woodcuts, has no rival; but he rendered no less service by presenting his lore in the form of fiction. In his stories he was able to allow himself more latitude and to exercise more dramatic skill than was possible in his archæological volumes. His "Homo Sum" is more interesting as a piece of composition, for when describing the life of the early Christian Anchorites he had not such information as can be drawn from Egyptian paintings and other works. It must be owned that in reanimating the past he was more successful than Théophile Gautier when with the aid of Ernest Feydeau he wrote "The Mummy." Ordinary readers were not able to realise that Ebers was one of the most learned Egyptologists in Germany and that his romances were only recreations after his professorial duties in Leipzig. For nearly forty years he devoted his life to Egyptology, and none of his predecessors made the subject so interesting.

At last the contractors are able to advertise the sale of the materials of Vauxhall Bridge. It was better adapted from its appearance to be considered a Bridge of Sighs than old Blackfriars Bridge. With all its strangeness it only dates from 1816, and was designed by James Walker. The bridge cost 260,000*l.* to build, and was purchased by the Metropolitan Board of Works for 75,000*l.* It was then a toll bridge. Originally it was called "Regent," Lord Dundas, who opened it, having acted for the Prince Regent, afterwards George IV. The association with Vauxhall Gardens was, however, more powerful, and the bridge ceased to be called after the Prince. In 1881 Parliament gave power to repair and alter the bridge at a cost of 40,000*l.*, but no patching could make it suitable to modern requirements.

It is satisfactory to learn that the scheme for placing one of the clerks of the Science and Art Department at the head of what is now called the Royal College of Art has been abandoned. That office has been offered to Mr. Walter Crane, and accepted by him. Artists especially will be gratified by the appointment. Mr. Crane is not one of those gentlemen who contrive to gain reputation by the labour of assistants. He was always a working artist, and he has gained success in those fields which South Kensington should cultivate. He has been and is a decorator, taking the word in a comprehensive sense. His example will excite the ambition of teachers and students who work under him, and the results will, no doubt, be advantageous for the country.

The decision of the Lords Justices in Marrow *v.* Flimby and Broughton Moor Coal and Fire Brick Company, which was given on Wednesday, may have the effect of diminishing the number of actions taken under the Employers' Liability Act by making the position of sub-contractors more clear. A workman who was employed in sinking a shaft for which a man named Evans had taken the contract at a certain rate per fathom was killed. His wife brought an action in the county court not against Evans, but against the Fire Brick Company, and obtained a verdict for 234*l* damages. The Company appealed, and the Divisional Court entered judgment for them on the ground that the man was not in their employment, but in that of an independent contractor. The plaintiff appealed, but without success. The Lords Justices held that the men employed looked to Evans for the payment of their wages, and to him alone, and he was therefore their employer in the terms of the Act. It was asserted that Evans was no more than a ganger, but that theory was not upheld. As no evidence was brought forward to show that the deceased man was a workman in the employment of the defendants when he met with the accident, and as there was no evidence to go to the jury in support of the plaintiff's case, the judgment of the Divisional Court was confirmed. The appeal was therefore dismissed with costs.

The House of Commons should exemplify the latest improvements in sanitation. Acting on that belief, or rather in order to ensure their own safety, the members of the House of Commons have caused large sums to be expended on drainage and other works. But the new works have not extended to the committee rooms, where private Bills are investigated. There are no appliances for the introduction of fresh air or the extraction of air that is vitiated. The occasional exhibitions of ill humour which occur between counsel and witnesses may be partially due to the condition of the rooms, which becomes oppressive especially when there is a crowd assembled, as in the case of Irish Bills.

In Glasgow progress is admired, but we hope there is no intention to imitate the go-aheadness of America by the erection of cloud-capped blocks of offices. A few weeks ago application was made in the Glasgow Dean of Guild Court to erect an eight-storey building of about 100 feet in height in Waterloo Street. The building would appear almost diminutive if compared with some of the sky-scrapers in American towns. However, the Dean of Guild referred to the great height of the contemplated structure, and to the risk to the public and adjacent buildings in the event of fire. The Master of Works, it appears, had pointed out that the water supply would not rise to such a height. Subsequently the neighbouring proprietors lodged objections to the plans on the ground that the titles provided that the buildings on the site should not exceed four storeys above the street, and that the walls, so far as fronting Waterloo Street, should not be more than 52 feet in height. There was a postponement of the decision, but at the last meeting of the Court the Dean of Guild declared that he could not uphold the objections, and that he had no alternative but to grant the permission that was craved. Glasgow is rather notorious for its fires, and apparently there is great risk in raising a building to a height which cannot be controlled by the water supply, although that is of unusual abundance.

A very creditable story comes to us from New York. In that city Messrs. Carrere & Hastings have gained much reputation as architects, and there was no surprise expressed when they obtained the commission for the New National Art Club. They, however, remembered that art is a republic, and they considered that it was invidious to select them without an opportunity was offered to rival architects to try for the work. They accordingly proposed that some other architects of recognised ability should in a friendly way draw lots in order to discover if chance would give the preference to another firm. Generosity was rewarded, for Messrs. Carrere & Hastings succeeded in drawing the lucky billet.

In the parish church of Fittleworth, near Petworth, in Sussex, is a remarkable tombstone which the rector is anxious to have identified by archæologists. He writes:—"It has been described in guide-books as the tombstone of some 'Knight of St. John,' on account of the so-called Maltese cross worked on the upper face of it. If this is correct, there is nothing specially interesting about it. But I have from the first strongly suspected that it is British, and this opinion was unhesitatingly confirmed by Bishop Cornish, sometime Bishop of Madagascar, and formerly curate of this parish. If so, we possess in it an almost unique relic of the ancient British Church in Sussex, an honour which one would be proud enough to claim if it were beyond dispute. The stone was dug up from a depth of about 5 feet in the year 1870, when preparing the foundations of a part of the church then rebuilt. It is of local material—what we call Pulborough stone—about 50 inches long, 24 inches wide at the head, and 20 inches at the foot, and just 1 foot thick. The face has bevelled sides, and on it is worked an equal-limbed cross, 20 inches each way, with a shaft or blade 21 inches long, terminating in a point, the whole very rough and primitive."

CHARLES GARNIER.

ONLY a few weeks have elapsed since, in mentioning the success of a son of M. CHARLES GARNIER, who although an invalid won one of the prizes of the Institut, we referred to the vigour of his father. By one of the ironies of the conditions under which life is held, CHARLES GARNIER, who might easily be considered as a professional athlete, has suddenly passed away, and his delicate son will probably long remain to lament him. Paris has lost not only an able architect but her representative artist. The picturesque figure of CHARLES GARNIER appeared to be a necessity in any assembly where the arts were recognised. It was no less essential in any picture which was intended to suggest the intellectualism of the city for his strongly marked features to be introduced. Many qualifications were required to attain so much prominence, and they were united in the architect. He was a Parisian by birth, he won his position by merit, he was witty, good-natured, capable, but above all, he never made a pretence of taking things too seriously. To the last there was much of the *gamin* about him, and he spoke and acted as if he believed the streets of Paris were equal to a university in affording instruction to all who cared to learn. He had to contend with imperialist, communistic and republic an officials, but he contrived to hold his own against them, and to bring his Opera House to completion without any serious disturbance of his own idea. If within the last year he had to succumb in the arrangements for the introduction of engines for electric lighting, it was owing to a sort of conspiracy of dull people. Against stupidity, said the Greek proverb, the gods are helpless, and GARNIER was defeated because, for the first time, he was compelled to encounter authorities who were deficient in respect for art, and who were therefore invulnerable in a place where even the red-handed communists were susceptible.

But regret for his loss will not be confined to Paris. CHARLES GARNIER came nearer to being an universal favourite than any other man in the profession. There is no country where his name was unknown, and among the expectations which would have hold of foreign architects when arranging a visit to Paris in 1900, the chance of seeing and hearing GARNIER would not be the least important. There was a fascination about him which shows that the routine of an architect's life cannot entirely stifle imagination. There were architects no less able in Paris, but somehow their reputation was not widely spread, or they were supposed to be too potent and grave to allow of any familiarity on the part of a stranger. No artist in Paris had on that account to pay a heavier tax than GARNIER for the reputation he possessed, and his urbanity in receiving those who considered him to be one of the spectacles of the city could not be surpassed by an American President.

But while so many were ready to appreciate the man, they hesitated about giving commissions to the architect. CHARLES GARNIER found, like architects elsewhere, that the designing of a work which cost 35,000,000 francs was no recommendation to lovers of economy, or, in other words, to the majority of people who contemplate building. The late WILLIAM BURGES used to lament half cynically, half sadly, the want of confidence in him which the wealthy people of Cardiff displayed, in spite of the evidence of genius which all could see at the Castle. Numerous as were the new houses and business premises, there was no call on him for a design. The owners were afraid that he would involve them in expenditure on marbles, bronzes, mosaic and coloured sculpture, from which no profit would be derived, and consequently buildings were run up which, if economical, are not beautiful. In the same way CHARLES GARNIER was compelled often to see countless buildings arising which were designed by architects whose reputation did not extend beyond their own arrondissements, while he whose fame was supposed to be world-wide was without a commission in his office, or was merely consulted as a referee. In the latter capacity he too often acted under honorary conditions, especially in connection with projects of the Government or the Municipality. GARNIER was inventive, and he was always glad of an opportunity to talk freely about what was feasible in arranging buildings or fêtes. Once on his hobby there was no care about fees. His influence could be traced in many of the Paris buildings, although next to his great work the only building of any note in the city which he designed was a club on the Boulevard Saint-Germain.

Yet it was impossible to have a better advertisement of power than was to be found in the Opera House. It is by far the most important of modern French buildings, and rivals the Louvre in suggesting what architecture can do to embellish a city. It is not necessary to pay for admission to the Opera in order to appreciate the ability of the architect. The vestibule and staircase which all can see are sufficient. But it may be doubted whether the building will stand the criticism of a later time as well as the Louvre. It was built for an age when costliness was preferred to beauty, and in its excess of ornament, colour and gold it expresses the luxury of a period of decadence. For opera-goers who care to enjoy music it has not the best auditorium of the Continent, but it was intended for the gratification of the eyes rather than the ears. It is a gorgeous house where there are no shams, for in all that dazzles and fascinates the most expensive materials are employed. The public money was laid out as liberally on the building as in an earlier time it was on the cathedral. The Opera House was a type of modern Imperialism ; it was generally accepted as such, and consequently, when the group representing *Dancing*, by CARPEAUX, was desecrated by means of a bottle of black stain, everybody concluded that the writing on the wall was visible, and that Bonapartism was at an end. NAPOLEON III. deserves credit for what was done by VISCONTI and LEFUEL at the Louvre, but what will be most generally accepted as the memorial of his reign was raised by CHARLES GARNIER.

Bonapartism, as we are repeatedly told by its representatives, is only a consolidation of the forces produced by the first revolution, and therefore is based on equality. The Opera House was to be a palace where the Emperor could meet his subjects without the restraints which tradition prescribed in the Tuileries. Consequently there was only one staircase for grandees and "gods." In a constructive sense that is not a safe arrangement, for the French are as liable to panics as the rest of men, and a couple of years ago, when the gasalier in the house broke down, a catastrophe was very nearly occurring on the staircase. But the common approach was supposed to be as effective an aid to Imperialism as a pamphlet by DE LA GERRONIÈRE or ABOUT, although it could not save the doomed system.

In another sense especially the building is a memorial. Many of the Paris improvements were set about with the intention of keeping the working-classes quiet by providing them with occupation. The extent to which subsidiary arts are introduced in the Opera House testifies to the same belief in co-operation as a political agency. CHARLES GARNIER'S ability is seen in the manner of combining them to produce a harmonious result. He resembled the conductors who were subsequently to officiate within the house, and make a variety of performers subservient to their desires. They could not be successful without acquaintance with the capability of every instrument, and GARNIER'S employment of sculpture, painting, gilding, reveals the genuine architect, the chief of the artists who controlled because he understood. In most theatres what is ornamental too often suggests something that is applied, and could often be removed without much detriment to the architecture. The busts, masks, symbols, amorini, musical instruments are as necessary to the completion of the architect's meaning in the Paris Opera House as the larger groups of sculpture. They are not supplementary, but seem to grow out of his original idea and to be inevitable. The manner of employing sculpture is enough to demonstrate how much was gained by GARNIER through his early exercises in the art. Notwithstanding the amazing variety which comes from the introduction of so many decorative elements, the whole building impresses one as no more than the realisation of a first thought.

In fact, there was so much haste about the earlier stages of the project, there was little time allowed for experiments or alterations. When the site became available through the street improvements, the Emperor appeared to be afraid it would be utilised for a building of a different sort. The competition was hurried. When GARNIER was selected he made a sort of flying visit to foreign theatres before preparing definite plans. But, owing to the expedition employed,

in less than nine months after the announcement of the competition the foundations of the building were commenced. In 1861, when so onerous a task was undertaken by CHARLES GARNIER, he was in his thirty-sixth year. His training resembled that of the ordinary Prix de Rome winner. He had travelled in Italy and Greece, had measured and prepared plans for a Temple of Jupiter, and made a series of admirable water-colour drawings of ancient buildings in Naples and Salerno, to illustrate a book by the DUC DE LUYNES, which was never published. Still he was poor and without patrons. On his return to Paris in his twenty-ninth year he was glad to serve under BALLU in the restoration of the beautiful Tour de Saint-Jacques la Boucherie in the Rue de Rivoli, and finally was admitted among the municipal architects. But he was not favoured with opportunities to display constructive skill.

He was not long engaged at the works before his courage was tried. It was necessary to make excavations to a depth of about 70 feet, and in the course of the work springs were tapped which seemed to be inexhaustible. A concrete bed was laid under water, and it was not until towards the close of 1862 that the masonry could be commenced. GARNIER had a temporary house and offices fitted up on the site, and there he lived until the works were advanced. Under his constant supervision the construction was carried on, and after seven years the building was ready for roofing. Then the war with Germany commenced and the operations were suspended. The building was not, however, allowed to remain idle. French ingenuity was often exerted on it. The Opera House served as a military store, a hospital, a prison, a barrack, an observatory, &c. It could not be employed for such various purposes without suffering injury, but the wonder is that it was spared from destruction, for it was the most imposing building of the Empire. When peace was restored CHARLES GARNIER persuaded the Government to resume the works, and in January, 1875, the building was opened for performances. St. Paul's Cathedral is not stronger evidence of WREN'S toughness in meeting opposition with equanimity, and in overcoming difficulties more annoying than those arising from materials, than is the Paris Opera House for CHARLES GARNIER. Some of the battles he had to engage in are easily inferred by all who have had to encounter officials, whether temporary or permanent, for they are alike all the world over; but whenever the particulars are made known they will convince Frenchmen of the bravery of the artist they have lost.

His theatre at Monte Carlo is on a very small scale if compared with the Paris building. It is, however, almost as characteristic in expressing showiness and lavish expenditure. CHARLES GARNIER was essentially the architect for princes and millionaires who were indifferent to economy. For that reason the *bourgeoisie* were afraid to trust him. His remarkable series of buildings illustrative of the History of the Habitation, which were set up in the International Exhibition of 1889, served his interest as little as his theatres. Archæologists and architects of course did not accept the houses as indisputable examples of ancient dwellings from the days of the troglodytes, and the honest citizens concluded that CHARLES GARNIER was a scenic artist who preferred flimsy construction.

The habitations were however a proof of the thorough knowledge of architectural forms which GARNIER possessed. Although he never posed as an erudite scholar he was acquainted with everything that was even remotely related to his art. His books on the Opera House, theatres, habitations and art in general reveal more literary skill than is commonly found with men who do not make a profession of the *belles-lettres*. He was a capital after-dinner speaker, whose words set the table in a roar, especially when they took the form of verse and were pointed by expressive looks and gestures. In our reproduction of the large wall-painting, the *Union of the Arts*, by the late GUSTAVE BOULANGER, a portrait of CHARLES GARNIER is introduced, and he forms part of a group consisting of ALEXANDRE DUMAS fils, GERÔME, GUILLAUME, CABANEL, &c., none of whom could consider an intruder the able artist who passed away exactly fifty years after he had won the coveted Prix de Rome.

THE IDEAL IN ART.

THE expression "beau-ideal" is not often heard nowadays. Although no longer in use few would have the courage to say that the aim, quality, creation, or fancy signified by the words had ceased to exist. What has happened is that various other terms are now substituted for beau-ideal, and it must be said without any loss or gain to whoever employs them. The old expression occasionally helped to lead artists and amateurs astray, but with a different phraseology we are not necessarily secure about always keeping on the right track.

What did the beau-ideal signify? We cannot always be sure about the definitions which were accepted by people who lived in a past age, but apparently there were at least two significations for the phrase. One would mean the more or less hazy vision of a form which appeared before the mind's eye, but which could not be always represented by the hand. When RAPHAEL said his figure of GALATEA was to be painted from a mental conception alone, when DA VINCI allowed the space on the Milanese convent wall to remain a blank because he was unable to realise the vision of the head of CHRIST, which was always coming and going; when MULLER the engraver first thought of suicide while engaged on his plate of the Sistine Madonna, because his hand was powerless to represent the black and white version of the original, with which he was haunted, they all had a perception of a certain form. One school of psychologists would say the artists must have seen such a form with their bodily eyes, but neglected the opportunity to make a sketch of it, for there could be nothing in the mind which did not enter through one or other of what JOHN BUNYAN called the Five Gateways of Mansoul. FUSELI was of the same opinion when he asserted that "our ideas are the offspring of our senses: we are no more able to create the form of a being we have not seen, without retrospect to one we know, than we are able to create a new sense."

The beau-ideal was also said to be the form which was made up of the most perfect parts of various objects or individuals of the same species. The Greek painter who was allowed to have a bevy of maidens in order to compile a single figure from them, was supposed to have gone in the right way to attain the beau-ideal. If he had first imagined a figure and then copied the models, as it were, for details, the Greek would not differ much from RAPHAEL or DA VINCI, except that his idea of attaining perfection was more mechanical.

When it is said that Greek statues of the great period or of the Periclean age are better adapted to help a painter or sculptor towards perfection than a collection of beautiful women, we see the influence of theories which treated painting and sculpture as if they were branches of mathematics and bore no relation to life. What is the ideal, the spiritual, the most perfect, but an extension of the geometric truth which believes that a line can have length without breadth, and a surface length and breadth without even infinitesimal thickness? It was a similar doctrine which affirmed that in architecture certain proportions were arrived at and were to be considered as infallible as long as men required to build. It was not realised that the proportions which were suitable in a region where the sky was always clear would produce a different effect in a country like England, where the light is often dim, and where the surroundings of an object must be considered in order to prevent an appearance of distortion. Men's eyes also are subject to changes, and it is not impossible that the impression which Greek statues and buildings make on us is not identical with that which was enjoyed by the Athenians when the works were first produced. REYNOLDS was honest enough to confess that he did not appreciate the works of RAPHAEL when he first saw them in the Vatican, and in spite of all he said in praise of them at a later time, they do not appear to have had the least influence on his practice as a painter. If the fear of being considered as wanting in taste did not prevent men from being frank, a great many of them would side with REYNOLDS in speaking of the Roman pictures, and would be no less doubtful about the perfection of works by more ancient architects and sculptors.

But there is another cause besides those which arise from difference in atmospheric conditions and physical

changes to prevent us from enjoying the old ideals. It is the love of plain, simple truth. Why were the Tanagra statuettes prized so highly? Because in them it was imagined reality was resuscitated. The little figures which were deposited in the cemetery were assumed to correspond with modern photographs and to represent everyday life and the fashion of the time. The ideal Venuses lost much of their fascination, for we were not akin to them, while the statuettes were taken to be relations of our sweethearts and daughters. In the same way the Egyptian portrait statues of scribes and overseers were preferred to the hosts of figures which were idealised according to hieratic canons and were executed under the eyes of the priests. It was a satisfaction to make acquaintance with the brawny overseer, for he corresponded with the builders' foremen, who stand no nonsense from anyone employed under them, while the figures usually represented by the Egyptian sculptors and painters have as little individuality as geometrical diagrams. Men have been so long the victims of theories, by a reaction they prize everything which bears the stamp of reality. They would therefore be better pleased if they could have veritable portraits of the five Croton girls who posed as models for Zeuxis than the Helen of Troy he deduced from them. Few modern painters can be so fortunate. Their goddesses must generally be fashioned with the aid of a single model, and the idealisation often consists in transforming into their original condition the lines which time has taken long to form.

It has been supposed that the progress of art is from the real to the ideal. First, objects are represented, if not with servility, at least without much discrimination; secondly, there is choice of objects; and thirdly, there is an imitation or collection of elegant extracts. In truth, the earliest art comes nearest to the ideal, for the representations are not faithful to the characteristics of the originals. If little reality was attempted by the Greek sculptors and painters, it was not altogether owing to their ambition to surpass nature in order to suggest the appearance of the gods and deified heroes. The aversion to the introduction of portraiture in such subject was also potent with the artists. The inane smile we see on the faces of the Æginetan figures and the expressionless features of the statues of a later period could not have been dictated by any canons prepared by artists. The peculiarities were more likely to be due to amateurs who, if wanting in taste and good sense, were possessed of power to make opponents suffer.

The Æginetan warriors were no doubt supposed to correspond exactly with the beau-ideal, and the sculptors may have imagined they were preparing models which after ages would be proud to follow. But the beau-ideal is, like everything else, subjected to the universal law of change. The figures that seem to delight in being transfixed with arrows were not more of a canon for all time than the special work of Polycletus, which was made with that intention. The Greeks corresponded with ourselves. They sought after novelty, and although they were restrained from possessing so many new things as we enjoy, they at least made it plain to all but the prejudiced that they were not conservative to excess.

The variations of sentiment about art which were exhibited during a period of little more than a century is enough to suggest that, with excellent materials to select from, there is no determining of an ideal. According to Winckelmann, there was no work to equal the *Apollo Belvedere*. He thought it was more of an abstraction than a piece of marble, the image of a spirit rather than a man. But it was supplanted in the favour of dilettanti by some of the Parthenon figures. The *Venus of Milo* had then its turn of supremacy, until the *Hermes* of Praxiteles was excavated. We hope many another masterpiece will appear to contest for acceptance as the beau-ideal.

If, as the psychologists teach, beauty is the expression of moral and spiritual perfection, what morecan be done at any time by mortal man than attempt an approximation towards that end? There must, therefore, be as many ideals as there are notions of what that perfection means. No two philosophers would agree in their definition of it, or of beauty. We may say that beauty consists in unity amidst variety, in power and order, in force alone, in the removal of the superfluous, in the imparting of qualities by which a beautiful thing becomes not only lovable but loving; but the attempt to define is like wandering in a maze without a clue and without a light. Followed out properly, what is called the science of the beautiful, a science which is exceptional in having nothing certain, embraces all philosophy and ethics—nay, it is by some made to comprise theology. It is melancholy to attempt to lay down a general law which will equally apply to things of which we can have no real cognisance, as well as to buildings, pictures and statues. It is much better to assume that we can only do what pleases us as individual legislators, and to allow others equal liberty. It is unsatisfactory, perhaps, but there must be as many beau-ideals as there are individuals.

THE ROYAL EXCHANGE.

UNDER the auspices of the Gresham committee and the Mercers' Company, Messrs. W. Cubitt & Co. are preparing niches on the walls of the ambulatory of the Royal Exchange for the reception of further mural decorations. The following scenes will form the subjects of the various designs:—William the Conqueror granting a charter to the citizens of London (Mr. Seymour Lucas, R.A.), the gift of the Corporation; the opening of the Royal Exchange by Queen Elizabeth (Mr. Ernest Crofts, R.A.), the gift of the Mercers' Company; the Crown of England being offered to Richard III. at Baynard's Castle (Mr. E. Goetze), the gift of Mr. Carl Meyer; a scene from the Great Fire of London, 1666 (Mr. Stanhope Forbes, A.R.A.), the gift of the Sun Fire Insurance Company. These pictures are fixed by Messrs. Charles Roberson & Co.'s new process of "Marouflâge," and are painted on a new medium-termed spirit fresco. The colours ground in this medium are used in a somewhat similar manner to ordinary oil colours on a specially prepared, highly-absorbent canvas, which, when the picture is finished, is laid solidly on the wall. It is expected that the Lord Mayor will unveil these panels in September, and it is stated that the cost of each is upwards of 500*l*.

HUTTON CASTLE, BERWICKSHIRE.

FOR some time past Lord Tweedmouth has been carrying out improvements upon the ancient historic building known as Hutton Hall, Berwickshire, the name of which has been changed to Hutton Castle. Hutton Hall is one of the most interesting edifices that remain in the soil of Berwickshire. Long under the feudal influence of the noble family of Home, it was granted by its chief in the fifteenth century to the Kerrs of Samuelton. It was one of the places in the district stormed by Gloucester during his disastrous inroad in 1742. After the fatal battle of Flodden it came into the hands of Home of Manderston, one of the Seven Spears of Wedderburn alluded to in the "Lay of the Last Minstrel" as coming to the aid of Branksome. He was deputy warden of the Marches, and his armorial bearings are still displayed on a mouldering stone over the principal doorway. The place is alluded to by Ford in his dramatic chronicle of Perkin Warbeck, who makes Surrey, the English general, taunt the Scots with allowing its glory to be diverted and yet not peeping abroad to retaliate. In later times it became the possession of the Johnstons of Hilton, a family who, deriving their origin from Annandale, rose, flourished and decayed on the soil of "The rich Merse." Here for a long time they maintained their territorial state. Within its walls, in all probability, was born the fairest daughter of the race, the celebrated Miss Lucy Johnston, afterwards Mrs. Oswald of Auchincruive, whose amiability and accomplishments inspired the muse of Burns in his "Wat ye wha's in yon toun," and whose mild, delicate and beautiful features, as they look from the canvas of Raeburn, are yet potent to raise the admiration of one sex and excite the envy of the other. There are other and not less interesting traditions relating to this old and time-honoured pile, but it would require much space to recount these in detail. Lord Tweedmouth has effected extensive additions to the historic building, so as to make it a residence in Berwickshire during certain seasons of the year, and Mr. G. George Duns, of Duns, the architect, has displayed great skill in carrying them out in order to preserve as much as possible the original character of the architecture. The old tower has been made habitable, the centre portion of the building has been raised one storey and four pepper-box turrets placed at the corners; the west wing has been extended and a new range of kitchen offices added. Lord Tweedmouth has made two new approaches to the building, the one from the west by way of Berwick or Chirnside across the Whitadder at the Blue Stone Ford; and the other from the east of the castle by way of Berwick, or through the Whitadder by Edington Mill Ford. At the west drive a handsome lodge has been constructed

ROYAL SOCIETY OF ANTIQUARIES OF IRELAND

THE Royal Society of the Antiquaries of Ireland last week visited the ancient territory of Hy-Fiachra, of which Ballina, co. Mayo, may be said to be the modern capital. In the immediate neighbourhood of the town the districts extending from both sides of the river Moy are studded with memorials of prehistoric and Christian times. Cromlechs, primitive churches, holy wells and tumuli are quite numerous within a circuit of a few miles.

The ancient church of Kilmore-Moy and its surroundings received much attention. This memorial is coeval with the early days of Ireland's Christianity, being founded by St. Patrick. The site is full of associations of the national apostle. A huge stone, which crowns the summit of the declivitous graveyard, is inscribed with an encircled cross, wrought, it is said, by the saint's own hand, and identified as being the "standard of salvation" referred to in the annals of his life, displayed by him on this hilltop when he first visited Hy-Fiachra. The sacred emblem is most distinctly traced, and reveals a striking amount of ornamental detail in its design. Beside the roadway leading to the churchyard is the Saint's Well, still greatly venerated, while at a little distance from it, beside the waters of the stream flowing from the well, is the site of the Princess Ectra's tomb, which the annals poetically tell us stood close to the sparkling spring, "a fitting place for the grave of a queen." The cromlech or tomb of the Meels is a ponderous table-stone some 10 feet in diameter resting on three single supports. A paper was read by Monsignor O'Hara, dealing at length with the tragedy this memorial commemorates. Though miles apart, it stands in sight of "Ardnareagh," on "the Hill of Execution," where four chiefs suffered death for murder. Subsequently the ruin of the old Priory of St. Augustine was inspected. The western doorway, formed of deeply-splayed mouldings, wrought in limestone and ornamented with crockets, is an example of late fourteenth-century work. Almost adjoining is the Roman Catholic cathedral, the spire and tower of which form a striking feature in the general view of Ballina. Interiorly the effect of the building is imposing, the characteristic depression of its style being somewhat increased by the pervading gloom caused by the stained-glass with which the cathedral is filled.

Rosserick Friary, some four miles distant from Ballina, was next visited. The drive thither, from the varied character of the scenery it affords, is strikingly impressive. The ruins of Rosserick are in excellent preservation, the foundation being rather late, dating from 1400. When the priory and church were erected and endowed by a member of the Joyce family for the Third Order of St. Francis, the members of this grade of the Franciscan Order, being of the less strict observance, devoted themselves to literary pursuits and education of youth, in addition to their spiritual ministrations. At Rosserick the Franciscans, as in many other places, seem to have retained possession of their home for a considerable time after the general suppression of the monasteries, as the schools existed down to the close of the sixteenth century. The priory and domestic offices are of the usual type adopted by the Franciscan Order. Here, however, the tower and chancel arch, which in many other convents were insertions or afterthoughts, form part of the original plan. From the excellent workmanship and materials used the effects of time have been frustrated. Though roofless, many portions of the building are as perfect as if they had only just been vacated.

The next object of interest included in the excursion was Moyne Abbey. This convent (as Franciscan settlements are correctly designated) is beautifully situate, being built close to the sea, at the mouth of the river Moy, about a mile distant from Killala. This once magnificent church and group of conventual buildings were founded by a member of the family of De Burgo, A.D. 1462. The ancestors of this illustrious house were among the Poitevin favourites of Henry III., who secured large possessions from their royal patron in many parts of Mid-Western Ireland. The military achievements of the first De Burgo were often marked by the devastating of the Church lands and monasteries of the ancient Irish, while with rather consoling inconsistency they are frequently recorded as founders of religious houses, and as giving many illustrious members to the Dominican and Franciscan orders. De Burgo, Bishop of Ossory, the Dominican historian, came of this noble line. The family is now represented in the earldom of Clanricarde. The situation of Moyne Abbey allowed ships of heavy tonnage in its time to moor at high water close to its very walls, opposite the island of Bartagh. The plan of the convent being so distinctly traceable, the Moyne may be said to supply the key to the construction of many of its more ruinous sister houses scattered so numerously over Ireland.

Thence the excursionists trended towards Killala, which ancient town lies north of Ballina, at the head of the bay that bears its name. The line of coast adjacent is varied and broken by bold headlands and deeply-indented bays and creeks. Between Kilcummin and Downpatrick Heads stretches a fine tract of country known as North Tirawley, on the shore of the Atlantic seaboard here. About a mile from the shore was part of the conventual property, and although so far distant could be reached by fjord at low water. In the thirty-seventh year of Elizabeth's reign this friary and its possessions were granted to Edmund Barrett at the annual rent of five shillings. However, as we have said regarding Rosserick, the Franciscans occupied the place for many years afterwards, paying an annual rent to the grantee. This was discharged by Sir Thomas de Burgo, knight, the munificence of whose family to the friars of Moyne continued from the beginning to the end. The vicissitudes and sufferings of the last inmates of this convent fill some of the saddest chapters of the chronicles of the Irish Franciscans. From an architectural point of view Moyne Abbey is most interesting. There is much in it to remind travelled visitors of Adare Convent, co. Limerick. Like the latter, as one lingers over all its features of loveliness, little touched by time, it seems as if some mysterious hand has just stolen the roofs away, and might perhaps return and drop them back in their place once more.

THE EGYPTIAN BARRAGES WEIRS IN 1898.

AS a commencement to the work of building the subsidiary weirs at the Barrages near Cairo, which will be taken up vigorously on the falling of the Nile after the flood of this year, some very interesting work has been done this summer. These weirs are designed, says the *Scotsman*, to hold up about half of the total head of water that will in future come on the Barrages when they are closed. The level of the water upstream of the Barrages will be allowed to rise 2 metres higher than is possible at present with the lowest water level downstream. This will give a total difference of 6 metres between the water-levels up and downstream in place of the present 4 metres. As 3 metres of the full head will be ponded up between the old and the new works, the actual strain on the former will be diminished, while its efficiency will be largely increased. The new weirs will traverse the river about a kilometre below the present works, in lines parallel to them.

The experience gained during the repairs to the Barrages, carried out immediately after the British occupation of Egypt, showed that the founding of a large work on the bed of the Nile at that neighbourhood would be a very difficult and costly undertaking, if carried out in the ordinary way by drying the foundations. It was decided that the core walls, on which the water-tightness of the structures will depend, should be built without lowering the surface of the water. The weirs are composed of a mass of dry rubble, with gradual slopes on the up and downstream faces. In the heart of the weir, and at the foot of the downstream slope, are two cores of solid masonry. Downstream of the lower wall is a large mass of stones, none of which are less than 2 tons in weight. These last will take the scouring action of the water passing over the weir, and will keep the river from cutting back the bed under the weirs. For the building of the walls the bed was first dredged out to the required depth. A case of sheet piling, of the exact dimensions, of a length of about 9 metres of the wall, was fixed in position and strengthened by large piles driven down outside. This was filled to the surface of the water with stones, and cement grout was run in by means of vertical perforated pipes, standing at intervals in the mass, in order to fill up all the interstices and to form a solid block. To prevent the grout finding its way through cracks or joints in the piling, the sides of the case were lined with a large continuous sheet of sacking. The foot of this was turned back along the bottom, so as to make a tight joint with the ground. A diver arranged this sheet under water, placing stones on the turned back portion to keep it in place till the mass of rubble was tipped in. The cement was mixed in long iron troughs, radiating to the pipe into which it was to be poured. It entered the trough at the outer end, and water was added. As it was turned over by men stationed along the sides of the trough, it found its way to the inner end, where it was lifted out in a liquid state, in a convenient position for being at once poured down the pipe. It was endeavoured to keep a steady stream of cement flowing down the pipe, and to this end a smaller pipe, with no perforations, was kept inside the other, discharging the grout just above the level of the cement already down. This small pipe had a funnel to facilitate the pouring of the grout, and a wire screen to keep lumps of unmixed cement and pieces of paper from the lining of the cement barrels from going down.

When one block was finished and the cement had set the piling was removed and the case set up further along the line of the wall, the end of the first block now forming one side of the box. The same operations were then repeated. Various mixtures of different sizes of stones were tried, with a view to lessening the contents of the spaces between the stones and economising cement. At the same time care was taken that

the interstices were not choked up so much as to prevent the grout from finding its way to all parts of the mass. This was seen by the way the level of the cement rose in other pipes than the one which was being filled at any moment. The experience thus gained will prove very useful when the work is attacked on a large scale next year. At each side of the main wall the triangular space formed by the side of the wall and the sloping side of the dredged trench was filled with good clay to a height somewhat above the original bed of the river. On this the dry rubble was laid, the weight of which, pressing on the clay below, will tend to consolidate it and to stop leakage below the wall. Above water the building was done in the dry in the ordinary way. Only about a fifth of the length of the weir across the Damietta branch of the river has been done this year, and a cross wall has been run between the two others to finish off the season's work strongly.

The work will be left in this condition to stand the action of this year's flood, and an examination on the falling of the water will show whether the trust placed in this simple and expedient method of construction has been justified.

PROFESSIONAL ETIQUETTE.

THE following is the substance of suggestions offered by the Société Centrale of French Architects for the guidance of members on their relations with other architects, contractors and clients :—

As "the artist who designs buildings, determines their proportions, arrangements, decorations, causes them to be erected under his orders and controls the expenditure upon them," the architect practises a liberal profession, not a commercial calling. His position is incompatible with that of contractor, manufacturer or furnisher of material in any way, and he is compensated entirely by fees to the exclusion of every other source of emolument resulting from his work or the exercise of his powers. If, therefore, he has taken out a patent for a product connected with building he does not exploit it himself, but sells it and all proprietary rights in it. Not being engaged in a commercial calling, he does not have any dealings which involve discounts or commissions, either received from those who wish for his patronage or given by him to agents and solicitors for capitalists or others whose patronage he himself desires. Nor does he seek publicity by advertising his capabilities in a commercial manner. In general, the architect must have no dealings with anyone of those dealings must be a secret between him and his clients, either actual or prospective.

The architect refrains from hostile criticisms, and does not aim at a situation or connection obtained by a *confrère*. If by the death, retirement or dismissal of an architect another architect is called to take up his work, the new architect considers himself as the guardian of the honour and interests of the former one. An architect recognises the condition of brotherhood in the profession ; he is careful to let the rules of consideration between equals govern all transactions between architects, such, for example, as arranging that meetings between architects shall be held in the office of the oldest without reference to standing of success. In the same way an architect treats young men obtaining their professional training in his office as members of his profession, and lets them have the full benefit of his experience.

In his relations with his client the architect devotes to him all his knowledge, and gives opinions and counsels with entire regard to advancing the interests committed to his care. At the same time the architect does not allow his client to exact from him operations which would injure the rights of others, or which would compromise his client himself, or which would bring about accidents. In these cases he warns his client that he cannot fulfil his wishes. He also warns his client when his instructions are such as to increase the proposed expense of his work. He gives from beginning to end a clear statement to his client of what is proposed by the plans and what the estimates and tenders come to, and forwards to him all accounts when he has verified and corrected them. He is remunerated by his client and by his client only, without receiving anything from any one else connected with the works. Even when the works involve services to another person the fee based upon this expenditure is paid by his client, who recovers the amount from the other party or parties. In matters of litigation an architect declines to act as an expert in a matter in which one of his clients is a party. He declines to act as expert if he has already published an opinion upon the matter in litigation. If he is nominated as expert by a client, as, for example, in a question of insurance, he ceases to become the agent or representative of his client, and becomes merely an expert.

The architect is fair and disposed to smooth the work of contractors as much as possible, but, as before said, he has no dealings with them which place either them or himself under money obligations one to another. He deals promptly and openly with all accounts between them and the owners, but does not pay them unless he receives a special commission from his client to do so. When an architect has a contractor or body of contractors as client, he is remunerated by fees in precisely the same manner as by any other client, and does not become involved in any element of commercial speculation which may be connected with the work. An architect who becomes a contractor or the clerk of a contractor loses the quality of architect. He does not lose this in becoming the clerk of an architect.

EDINBURGH MUSEUM OF SCIENCE AND ART.

THE subjoined report was prepared by the director of the Edinburgh Museum for 1897 :—

The large room in the north-east angle of the building into which the lecture-hall is being converted is approaching completion, and will soon be available for exhibition purposes. It will be appropriated to furniture and wood carving, the specimens of which have hitherto been more or less scattered in different parts of the museum. By the removal of those which were formerly placed in the north corridors of the great hall an improvement in the arrangement and classification of architectural casts, &c., has become practicable. The north-west corridor has now been appropriated to Indian and the north-east one to Renaissance casts and reproductions. The collection of economic botany has been entirely rearranged in natural orders in long ranges of suitable new casing that occupy the greater portion of the upper gallery of the great hall. The old casing in the textile gallery has been entirely overhauled and made practically dust-proof. The collections it contained, illustrative of textile materials, processes and products, will now be rearranged, and where necessary supplemented or renewed.

Considerable additions, both by purchase and gift, have been made to the art industry collections in the course of the year. Among the purchases may be mentioned the following :—Ten specimens of silversmith's work, embracing casters, candlesticks, paten, &c., English and Italian. A Persian *kalian*, or hookah, in silver and enamel. Eleven specimens of sewed work, comprising a long linen cover embroidered in silk, seventeenth century ; a piece of blue linen stuff with representation of Daniel in the lions' den, from an ancient tomb at Akhmin, Egypt ; and examples of embroidered fabrics from Alosno, Andalusia, eighteenth century. A Scottish basket-hilted sword of the early part of the eighteenth century. A table made of various ornamental Scottish serpentines. Four electrotypes of parts of the shrine of St. Simeon at Zara, Hungary. Series of 199 photographs of the Bethnal Green loan collection of English furniture of the seventeenth and eighteenth centuries. Series of 427 photographs of the silversmiths' work in the South Kensington Museum.

Plaster casts as follows :—Statue of Gudea (Chaldean) ; statue of Sheikh-el-beled (Ancient Egyptian) ; Sopra Porta of south sacristy of Milan Cathedral ; woodwork from the Peyre collection ; statues of Mausolus and Artemisia, from the mausoleum, Halicarnassus ; Assyrian bas-reliefs and classical busts ; five bronzed bas-reliefs after R. Caldecott.

Model reproduction in wood and plaster (scale, two-thirds of original) of Paradiso apartment of Isabella d'Este at Mantua.

Terra-cotta reproductions of Etruscan chair, and statuette of boy with dolphin, by Verrocchio.

Large and important additions to the section of ethnography, the most noteworthy being a representative series of the native weapons of the Dutch East Indies ; an interesting general collection from Tibet and Sikkim, and valuable additions to the collections illustrative of the New Hebrides, New Caledonia and America.

Among the gifts may be noted :—Cabinet of rosewood and ebony inlaid with ivory, Indo-Portuguese of seventeenth century ; five painted Urbino majolica plates, by Orazio Fontana, about 1540 ; three Chinese blue and white porcelain vases and a Cinque-Cento group in silver gilt, enamel and distorted pearls, given by the Misses Forbes, of Callandar House, Falkirk, in accordance with the wish of the late Right Hon. Lady Jane Dundas. Old charter chest of the Græmes of Inchbraikie, given by Colonel J. P. Robertson, C.B., Callandar Lodge, Callandar. Large model of a Baghla or native Persian Gulf sailing vessel, given by Mr. G. S. Mackenzie, C.B., London. Piece of fifteenth-century wattle-work from Holme Farm, Bumworth, near Bolton, given by Mr. W. W. Midgley, Chadwick Museum. Native objects from Samoa, including a robe laid upon the bier of Robert Louis Stevenson by Tupuola, chief of the Tanugamanono, Upolu, given by Miss Balfour, Edinburgh. A collection of Chinese pictures and maps, given by Mr. W. F. King, F.R.S.E., Trinity.

The following bequest has also been made :—Swiss carving of "The Last Supper," after Leonardo da Vinci, in ebonised

case, bequeathed by the late C. M. Kerr, 11 Dean Terrace, Edinburgh.

The chief work done in the Geological Survey collection has been the rearrangement of the specimens of rocks, with the object of incorporating specimens of particular interest, revising the nomenclature and gaining exhibition space for districts not previously represented. Many specimens have been examined by the petrographical staff of the Survey, and sent to the museum. Some additional specimens have been sent in by the field collectors, and a large number of others from various Scottish localities have been selected for exhibition from the Heddle collection. By judicious selection and arrangement it has been found possible to insert these and to make room for rock specimens from five of the Scottish counties not previously represented. As soon as any new publications of the Geological Survey appear they are placed in this gallery for the use of the public. Some improvements in the mode of exhibiting the survey maps have been carried out in connection with six of the counties.

The principal work done in the Scottish Mineralogical Collection has been the transfer from St. Andrews of the late Dr. Heddle's various residues of his collections of rocks and minerals. Amongst these are many specimens of rocks from Scottish localities which are in general difficult of access. These, labelled as part of the Heddle collection, have been incorporated with the general collection of rocks. But the greater part of this residue consists of duplicate specimens of Scottish and other minerals, which Dr. Heddle gave to be used in exchange for Scottish rocks, minerals or fossils for this department of the museum. The list of specimens is too long for insertion here ; but among specimens of particular value may be mentioned several examples of abriachanite, thorite, allanite, harmotome, brewsterite, mountain leather, brucite, prehnite, xantholite, serpentine and others. As the second edition of the guide to this department was out of print, a third and enlarged edition (Part I., Geological Survey Collection) was prepared, and is now on sale in the museum. Part II., Scottish minerals, is being proceeded with. In addition to the Heddle donations already referred to, others of interest and value have been received.

The additions to the library by donation and purchase amounted to 621 volumes, besides pamphlets. The principal donation was one of 299 volumes of works relating chiefly to mineralogy, geology and chemistry, given by Dr. M. Forster Heddle, Emeritus-Professor of Chemistry in the University of St. Andrews, and since deceased. Among the other donors were the Governments of France and the Netherlands, the Prefect of the Seine, Paris, and the authorities of the India Office, British Museum, Science and Art Department and Smithsonian Institution. The patent library received, as usual, the various publications issued by H.M. Patent Office, as well as the specifications of United States patents. There was a slight increase in the number of visitors by whom the library was consulted during the year. A classified catalogue of the publications in the library (including the Cleghorn Memorial Library) relating to botany and forestry was issued, and is now on sale at the museum, along with the following library catalogues, previously published, viz.:—Architecture, Arms and Armour, Furniture, General Catalogue of the Library, Glass, Pottery, Textiles and Costume.

SUSSEX ARCHÆOLOGICAL SOCIETY.

ON Monday the annual excursion of the Sussex Archæological Society took place, but the proceedings were deprived of some interest by the rain. There was, however, a large attendance of members and their friends. The first rendezvous was Bexhill railway station, whence the party was conveyed in brakes to Ashburnham Church. The visitors were received by the Earl of Ashburnham and conducted to the church, the archæological treasures of which were exposed to view. These included the massive communion plate presented to the church by its founder, John Ashburnham, groom of the bedchamber both to Charles I. and Charles II., and the parish registers dating from 1538. The chancel contains a curiously worded epitaph on this John Ashburnham, describing him as son of "that unfortunate person, Sir John Ashburnham." There is also among other memorials a fine sculptured tomb in memory of Jane, Countess of Marlborough, who married into the Ashburnham family, and whose virtues are extolled in a high strain. An account of the church was given by the vicar (the Rev. Charles Baker), who said there had probably been a church on the site from the eleventh century, though the present edifice was built in 1663. The special features of the architecture were the wooden mullions of the windows and the seven steps from the floor of the tower to the nave, and seven steps again from the nave to the chancel gave the altar a very lofty position.

In the hall at Ashburnham Place were to be seen the famous relics of Charles I., including linen garments worn by the unfortunate king, his watch, a lock of his hair, and the sheet which was laid over the body after execution. The authenticity of these relics is beyond question. The party were also shown Vandyke's portraits of the Duke and Duchess of Richmond and other family portraits of great beauty and interest.

From Ashburnham the party drove to Battle, where there was luncheon in the Drill Hall, under the presidency of the Earl of Ashburnham.

Battle Abbey was next visited. Mr. W. H. St. John Hope who had undertaken to describe the building, found it convenient to address the members from the shelter afforded by the noble gateway. The abbey, he explained, was founded by William the Conqueror as the tardy fulfilment of a vow made before the battle of Hastings. The site was on the very scene of the battle, and the high altar was supposed to have been placed on the very spot where Harold's body was found. The later history of the abbey was practically *nil*, except such as was written on its stones, for though part of it had been destroyed sufficient remained to enable them to put together a fairly intelligible story. The abbey he described as of the normal Benedictine type, and he identified the remaining portions of the building as the guest-house, refectory, dormitory, infirmary, locatorium, &c., pointing out the special features of each. He particularly called attention to the fine gateway, the beautiful twelfth-century work on the exterior of the guest house, and the ruins of the dormitory. The principal points on the field of battle were to have been pointed out by Mr. W. A. Raper, but owing to the continuous rain this portion of the programme was omitted, and the archæologists filed into the church, where the Norman font and the splendid monument to Sir Anthony Browne, master of the horse to Henry VIII., were centres of attraction.

The Very Rev. Dean Currie gave a description of the church from the historical point of view. He thought it improbable that there had been, before the conquest, a parish of St. Mary of the Wood, as had been said. The original Norman building, parts of which remained in the present church, was erected in 1187, as the monkish records showed for the people of Battle, whose attendance at the Church of St. Martin in the Abbey had caused to the monks "certain inquietude which they were unable to suffer without breach of order." Disputes then arose, he showed, between the monastery and the servants of the Bishop of Chichester, ending in a compromise under which a dean was appointed. After the dissolution of the Abbey the Deans of Battle retained their jurisdiction, and there were records of several cases tried in the decanal court. The late Bishop of Chichester was the first to hold a confirmation in Battle Church without signing the book kept for the purpose, in which he declared that he claimed no jurisdiction by holding such confirmation, and although the privileges of the Deanery had for the most part been taken away or allowed to lapse the Dean of Battle still held a position which was quite peculiar, having as vicar the cure of souls. Mr. J. Lewis Andre read a paper on the architectural features of the buildings, and the party proceeded to the Deanery, where they were entertained.

ANTIQUE FURNITURE IN FRANCE.

THE United States Consul at Marseilles, in a recent report to his Government, calls attention to a law dealing with curio and antique furniture dealers which has lately been issued. This law may be of service to the many strangers who visit France with the expectation of buying articles of the above description, possessing artistic or historic value. The vital feature of the law is the obligation now resting upon all brokers, dealers in old furniture, linen, clothes, jewels, books, dishes, arms and other articles to keep an official register, signed by the commissary of police or the mayor, containing "day by day, without blanks or erasures, the name, surname, character and dwelling of those with whom the said broker has contracted ; also the nature, quality and price of all said merchandise and said register must be forthcoming on demand." Penalties are prescribed for violation of the foregoing provision, the object of which is to prevent fraud in the exchange of old and second-hand goods, especially such as are sought by collectors.

The Thompson-Yates laboratories, Liverpool, are now rapidly approaching completion, and at the beginning of the winter session the professors of physiology and pathology will be in possession of the most adequate accommodation, both for medical teaching and for scientific research. The laboratories will be formally opened by the president of the Royal Society, Lord Lister, on Saturday, October 8.

NOTES AND COMMENTS.

The town of Colmar is in Upper Alsace, about forty miles from Strasburg. The Dominican church, which was erected in 1278, has been long used as a corn hall. It was designed in rather attenuated Gothic, and in consequence has suffered much during its use for secular purposes. The high altar used to be adorned by sixteen pictures, which were painted by Martin Schongauer; they have been removed to the museum. The church is considered to be of extreme importance in the history of German architecture, but during a restoration of the last century some of its most interesting characteristics were destroyed. It was used as a barrack and a fruit market before it was handed over to the corn dealers. It is now restored again, but in a style that is more in keeping with its original appearance, and it is believed to be one of the best examples of Alsatian Gothic architecture which has survived. The works seem to have been completed without any friction between the parties engaged. The restoration of the Minster of Colmar was conducted under different circumstances, and is now the subject of lawsuits which are likely to cause dissatisfaction to others besides the litigants.

If Irish antiquities are not made known to all who can read English, it will not be the fault of the Royal Society of Antiquaries of Ireland. A series of handbooks is in course of publication which are unmatched for cheapness and excellence. Although abundantly illustrated, the price is only sixpence each. The latest is mainly devoted to the coast of Clare, Kerry, Cork and Waterford. It is a remarkable region for archæologists, for in it are found prehistoric fortresses and those primitive oratories and monasteries which are unique. The oratory of Gallerus is a bee-hive structure, and although formed of dry stone masonry "is practically waterproof, the stones being laid so as to slope outwards." The ancient city of Fahan contains stone huts extending for nearly three miles. Their names cannot be called prosy, for among those given by Sir Thomas N. Deane are "the city of the course field," "the cell of the old inhabitant," "the cell of the big family," "the city of the glen of the slope," "the city on the big point," "the city of the western coast," "the fortifications of the rock," "the lair of the hare," and "the structure overlooking the other forts." There is a fine round tower on Scattery Island called after the Cata, a terrible monster whose portrait is represented on the gable of Kilrush Chapel, and another is at Cloyne. As a contrast to the old structures, there is the noble castle of Lismore, belonging to the Duke of Devonshire, which stands in a picturesque position beside the Blackwater River, and in a district which is the most prosperous in Ireland, owing to the generous administration of the landlord.

Of late years cases which related to the easement of support have not been frequently tried in the Law Courts. For that reason, as well as for others, much interest must be attached to the judgment of Mr. Justice North in Jordeson *v.* the Sutton, Southcoates and Dry Pool Gas Company. The plaintiff owns cottages in Hull, and on the adjoining land the gas company having entered into a contract with Messrs. Holmes & King, excavated a large tank which was to form the lower part of a telescopic gasholder, which was to be over 100 feet in height. The excavation was close to the cottages, and when carried down to a depth of about 37 feet the ground as well as the cottages subsided. It was alleged that the contractors had not adopted the best course for damming back the water and silt. The gas company relied on their statutory powers to supply gas, and claimed to be entitled to interfere to some extent with the plaintiff's rights. When the case was first heard in February the judge decided that the erection of the gasholder would interfere with the light to the cottages, but he considered that the work had been skilfully carried out. Judgment on points of law was postponed. A week ago his lordship held that there had been considerable damage to plaintiff's property by withdrawing the support, and that there was no legal justification for what was done by the defendants. Mr. Justice North, in considering the case of the contractors, set aside the contention that they owed no duty to the plaintiff. They were the persons who by their workmen made the excavation upon the gas company's land, the result of which was wrongfully to remove part of the plaintiff's soil, and thereby to cause the land above it to slip and subside, and so damage the buildings thereon. Nor did it matter how much care they took in what they did, if that care did not suffice to prevent the injury. If no amount of care could have prevented it, the act ought not to have been done at all. The plaintiff was entitled to damages for the injury which had been done, and his lordship assessed the amount at 340*l.* This did not include any damage for interference with light, nor any sum in respect of damages which might arise hereafter in consequence of any future subsidence which would give a new and separate cause of action. The injunction would issue against the company, and the damages would be awarded against all the defendants. There would be judgment against the company for the plaintiff's costs of the action, and against the other defendants for so much of the plaintiff's costs as related to interference with support and its consequences. The gas company will no doubt repay all costs and damages in which the contractors are mulcted, but cases might arise in which it would be held by co-defendants that contractors were bound to be responsible for all damages arising out of lawsuits. It will therefore be well for them to insist on the introduction of a specific clause absolving them from all liability for law costs or damages arising out of interference with the easement of support.

The Pavillon Flore cannot be converted into a temporary dwelling for the royal visitors who are expected to visit Paris to see the wonders of the exhibition of 1900. There will be apparently no special building in which the hospitality of the Republic will be displayed towards kings and queens. But as the idea of a palace of the kind is novel it was fitting for adoption in the Ecole des Beaux-Arts. The Prix de Rome, it was announced, would be given for the best design for a palace to be erected on the banks of the Seine at Passy, where sovereigns and other representatives of foreign States would be welcomed. A competition of the kind was almost of historic interest. It was won by M. Chifflot, who studied under MM. Daumet, Girault and Esquié. He is in his thirtieth year. M. Arfidson, who came next, is two years younger, and was a pupil of MM. Ginain and Scellier. Last year he gained third place. This year that position was attained by M. Aubertin, born in 1872, and a pupil of M. Pascal. Among the unsuccessful competitors were MM. Garnier (a son of the late Charles Garnier), Bigot, Hulot and Guadet.

The beautiful bases for masts in the Piazza at Venice are admired not only by visitors, but by all who have seen engravings of them. The New York Municipal Society has decided to have a base produced in similar style for the open space in front of the City Hall, New York, or it may be placed on one of the steps. The height will be about 15 feet, and the cost 3,000 dols., exclusive of the cost of the model. A sum of 400 dols. is offered as the first prize in the competition for the base, 200 dols. as second prize, and 100 dols. as third prize. Designs are also sought for a drinking fountain to cost about 250 dols., and of which large numbers may be cast for use throughout New York. Prizes of 250 dols., 150 dols. and 100 dols. are offered. It is to be regretted that we have not municipal art societies in England who will be equally generous and anxious for the amenity of public places.

CATHEDRAL SERIES—PETERBOROUGH: SANCTUARY AND HIGH ALTAR. SOUTH AISLE, LOOKING WEST.

PROPOSED OFFICES IN BISHOPSGATE STREET, E.C.

THIS design was prepared with a view to erect a portion of the front—viz. the two bays—from next Crosby Hall to the passage-way to Crosby Square, and the remaining bay, next the Bank of Scotland, to be a future addition.

89 AND 91 LAMBETH WALK, S.E.

ENGLISH HABITATIONS.

IT is not necessary minutely to describe the dwellings of the first inhabitants of our island. Thickets, dens and caves were their first retreats. Their next endeavour was to execute something more durable, consisting of stakes driven into the ground interwoven with wattles, built circularly with high tapering roofs, at the top of which was an aperture equally adapted for the admission of light and the emission of smoke. Large beams of wood, sometimes on stone foundations, began then to be used. There is no great fear of offending truth in conjecturing that the first erections beyond that style were built either by the Romans on their obtaining a settlement under the Emperor Claudius, or by those natives who had been at Rome as prisoners, or otherwise. The first colony planted by the Romans was at Camulodunum, which appears to have been a large and well-built town. The idea that London was built before this time is so faint that it is scarcely worth the inquiry; for, according to Strabo, what the Britons called a town was a tract of woody country surrounded by a mound and ditch for the security of themselves and cattle against the incursions of their enemies. Among the earliest regular erections in Britain were the chain of garrisons between the Friths of Clyde and Forth by Julius Agricola, and the wall of Antoninus, called also the Picts wall. Agricola is supposed also to have erected several temples, and as it is well known that he encouraged to the utmost the arts of peace, we may be assured he did not neglect private convenience. Architecture did not decline much after the departure of the Romans, who with unexampled ingenuity and address instructed their conquered subjects in all their arts, and thereby much benefited both parties. In the time of the Saxons, previous to the disastrous troubles of Hengist and Horsa, there were public and private edifices; but of what kind is not certain, neither would it be much to our purpose to inquire, for they were all destroyed by fire, rapine and plunder during that period. Drawing a few degrees nearer to something like authentic record, we find that about the year 480 Ambrosius, a British commander of Roman descent, who assumed the regal government of the kingdom of Kent, erected for himself and followers a "palace" at Canterbury.

During the Heptarchy, or as Sharon Turner more correctly terms it, the Octarchy, religious sequestration being much in vogue, churches and other ecclesiastical edifices began to multiply. The monks, the only architects of those times, erected those rude buildings now termed Saxon, which by their similarity in parts to the worst Roman, may warrant the conclusion that they designed them from the help of memory alone, and that the declension of pure architecture in Italy, and the still further depravity of style introduced by treacherous memories and a bad taste (which universally accompanies a want of knowledge in any art or science), finally produced those various styles of architecture observable throughout the whole of the more ancient English buildings.

The Britons under the Roman dominion had made such hasty strides towards art and manners that previous to the devastations committed by their furious Saxon invaders, they had erected nearly thirty considerable cities, besides a greater number of villages and country dwellings, most of which were destroyed and the natives thrown back to their former barbarism and manner of living. Nothing worth noticing except by the professed antiquary occurs till about the year 790, when Offa built and endowed the celebrated monastery of St. Albans in the town of that name, which was at that time a considerable city.

The new City of London in the reign of Alfred the Great, after the death of Burrhed the last king of Mercia, in whose territories it was situate, became of some importance, beginning to stretch itself along the banks of the Thames. This king's celebrated division of the country into counties, and incorporations of families for the distribution of justice and the prevention of crimes, caused villages, towns and cities to be crowded together. Courts of justice, religious consistories and meetings for the support of military discipline and civil justice added much to the splendour of the rising city which was repaired and beautified by Alfred himself. He also founded (or at least repaired) and made considerable additions to the university of Oxford. Cambridge began to assume a promising appearance; monasteries were daily increasing, both in number and splendour, among which that of Malmesbury in Wiltshire was one of the most flourishing, it being the custom of the times to bestow all the confiscated estates on the maintenance of such establishments. During the succeeding reigns from Alfred to Canute, a period of about 160 years, which in comparison with after ages may be termed enlightened, architecture flourished beyond any other before the Conqueror. Churches and cathedrals were erected, others restored and some rebuilt, and at Rome an English school was built by the last named king, who from these and other similar measures became very popular. In the succeeding reign of Edward the Confessor, excepting the first monastery at Westminster which was endowed by him, architecture was rather at a stand; the abbey at Waltham, founded by the unfortunate Harold, was a proof of his good wishes towards the embellishment of his country, but they were frustrated; and till after the death of that monarch, and the final settlement of William the Conqueror, scarcely a system of the architectural art appeared, excepting in those fortresses erected by him in London, Winchester, Hereford and other places most likely to suit his purposes, by their warlike appearance, to keep the natives in awe after disarming them and stripping their churches and monasteries to furnish a splendid court. He reduced almost all their edifices to a state requiring little less than total re-erection; till in his last illness he endeavoured to make some atonement for his devastations by large presents, gifts and endowments, which set the whole community of architects, builders, embroiderers, jewellers, &c., once more in action.

As for the short reign of William Rufus, there is more to be said than on a transient glance might be expected from so short a period, though from his character it does not appear that he was wanting in respect for the religion of his day, which was fond of exhibiting itself in foundations, erections and similar display of gaudy magnificence. The abbey of St. Albans, the Tower of London, Westminster Hall, London Bridge, and part of the Palace of Windsor are among the principal works of this king's reign, and may be produced among others as proofs of that assertion. The national architecture had assumed a fixed principle of design, and had settled into that style now called Norman.

The style of this period cannot be better illustrated than by the shrines which were carved with more labour than taste; pinnacles on pillars, canopies, fretwork, gilded and emblazoned decoration, crowded the interiors of those heavy Saxon buildings, and formed a curious contrast to the cumbrous circular pillars. England, like the rest of Europe, was now fast declining to a barbarous and gloomy period. Petty despotism, comfortless insecurity and gloomy suspicion erected the dark embattled castle, with its vast and gloomy apartments, its stagnant moat, guard turrets and drawbridges, while perhaps the greatest luxury was clean straw for the master's apartments. Vassalage and feudalism thinned the cities and destroyed the villages, and for ages architectural improvement was unknown. Cities began to assume a warlike appearance, and the abovementioned reason caused them all to be walled. The absence of their kings on religious warfare dimmed the splendour of their courts and paralysed the efforts of their artists. Magnificence was now only to be displayed in richness of apparel and the number and gaudy accoutrements of their followers. How then in such a time could the arts flourish? How could they advance in any degree towards their original purity, when they were more prized for the worth and cost of the materials they employed than as specimens of taste?

These enthusiastic warriors, once more quieted by a partial attainment of their object, turned their attention as formerly to ease and luxury; and as vehement spirits always rush into extremes, cloistering became once more in vogue, which, though not much changing the appearance of their dwellings, served at least to embellish and enlarge the monastic fabrics. The charter granted by Henry I. to the City of London in the year 1135, and his further confirmation of their privileges of courts of hustings, wardmotes, vestries and common halls increased the rage for building in the Metropolis, augmented the number of public edifices, and by promoting society and social intercourse banished suspicion, created mutual confidence, improved domestic comfort, and while the rest of the kingdom was still in alarms from the apprehensions of danger and the fear of offending the independent nobles, the Metropolis greatly improved in quiet and security.

Even the short and turbulent reign of Stephen assisted the cause of art in some degree; for the licentious and unbounded devastations and extortions of the nobles, the imitation of their stately superiors by the inferior gentry and the state of vassalage which it consequently introduced, sensibly swelled the list of independent castles and their appendages for the enslaved peasantry, becoming the original of a style now very prevalent, which has since obtained the name of the castellated style of architecture. Among the largest of these castles erected by these turbulent barons were one at Sherborne, one at Devizes, another at Malmesbury, erected by the Bishop of Salisbury in 1139, and one at Newark by the Bishop of Lincoln, which practice now became very prevalent among the dignified clergy, who followed the example of the secular nobility. Indeed, they now became so numerous and powerful that they almost threatened another division of the country. Humble private dwellings were destroyed, neglected or suffered to fall into ruins. Their greater neighbours shortly afterwards shared no better fate, for all the newly-erected castles, built during the reign of Stephen, were rased by his successor, the second Henry, in whose days architecture assumed somewhat of a less warlike style. Interior decorations and domestic comforts were more regarded, and by none more than by his luxurious primate Thomas à Becket, whose munificence is proverbial. But however grandeur, considered as consisting in costliness of ornament, might prevail,

certainly elegance and comfort would not be found by one of the present day in clean hay and straw or grass (according to the season) strewed about the apartments to prevent spoiling their sumptuous habiliments. Becket was a munificent patron of arts and genius ; in a defence against an accusation of having wasted the public money, he boasted of having repaired many castles, and particularly the Royal Palace of London, so that he certainly deserves a rank among a list of early English architects, for although his artist's name is now unknown, we ought at least to allow him the credit we do to some others of later date who have had their names appended to works more likely to be doubted than his. The style of our national architecture was now somewhat changed ; the homely erections of Saxon progenitors were exchanged for affectations of ornament, the ecclesiastical buildings stretched themselves into ramifications more complex than the course of the Nile.

It would be a curious, and by no means an absurd inquiry, to compare the resemblance between building, dress and manners. There is little doubt that the styles of the age here mentioned is strictly in point. In the times of Elizabeth and James the prim ruff and puritanical manners singularly accorded with the inelegance of their buildings—alike cumbrous and graceless ; and even now, to a mind attentive to such things, the analogy is no less perceptible.

The Crusades which followed in the reign of Richard Cœur de Lion were inimical to the arts, though it is not to be doubted that the king had a taste for cultivated pleasures, as he ranks among the troubadours or poets of the age, and also that poetry and painting (if we may call the introduction of armorial bearings by that name) were introduced with and by him into England. In the slothful inglorious reign of John nothing relative to our purpose is worth the trouble of recording except the celebrated excommunication by the Pope, which caused all the shrines, altars, chapels, sacellæ, sacristies, &c., to be despoiled of their ornaments, the statues of their saints to be thrown prostrate, and similar other spoliations, which provided the artists with more work when that restraint was taken off.

Henry III. was so straightened for money that it is no wonder we find few architectural records in his reign ; he squandered his property on favourites, and whatever they might have erected the art certainly did not make that progress that a reign of fifty-six years might have warranted ; yet he repaired, if he did not erect, Eltham Palace about the year 1270. Edward I. adds nothing to our collection ; his thirst for glory and his ardour in the crusades is sufficiently notorious to prevent much search. Neither does the second of that name add much more ; velvet beds, silk vestments, embroidered girdles, enamelled armour, jewels and plate were the favourite luxuries of his time. Arts and manufactures were low, the country from its foreign wars not very populous, consequently no advancement was made in Domestic architecture.

The reign of the third Edward is of much more consequence in our annals. The magnificent Palace of Windsor and many other buildings of a similar style were erected by him, which, considering the wars he was engaged in, reflects much credit on his memory. The style began to be more bold, simple and striking ; geometrical construction was well understood and the workmen were excellent ; every county was assessed for its quota of artificers in the same manner as for an army. It may be worth the mentioning that tolls for repairing roads were first imposed in this reign, and the first so repaired was from St. Giles's to Temple Bar. A master carpenter was paid 3*d.* per day, and a journeyman 2*d.* Edward IV. built Crosby House about the year 1468, as also the monastery of St. Helen, and repaired London Wall. The reigns of Henry V. and VI. were not in the least auspicious to the arts ; the glorious warfare of the one and the supine weakness of the other were alike prejudicial. The wars between the red and white roses encouraged none but the military fortified style, by some termed the Edwardian, which prevailed in all the erections civil and domestic that were raised under King Edward IV. In the Metropolis were now many rich merchants who lived in a style superior to the inhabitants of any other part of the kingdom, and in a few instances advances were made, but more on the side of gaudy magnificence than real improvement in the art. The taste for splendour, show and addiction to pleasure of this monarch produced much improvement in Domestic architecture ; but always frustrated in his schemes he acquired little more than the merit of introducing a style which was subsequently followed with more success than his turbulent times allowed. Hospitals that were ransacked in that reign were restored in this ; others were erected, but the style was still dark and gloomy, resembling castles and dungeons more than convenient dwellings, such as even before this period began to spread abroad from Italy, the centre of the fine arts, but it was left for after-times to receive their united blossoms.

London undoubtedly cultivated this national style more than any other part of the kingdom, and whatever was deficient in taste was amply compensated in expense by the wealthy citizens. Crosby House was a large and elegant structure, and the architects and workmen had acquired that facility of execution and improvement in style which are now the admiration of all true judges of geometrical construction. The shrine of William of Wickham, King's College chapel, Cambridge ; Ely House, Holborn, now no more ; the hall of Crosby House, the elegance and labour of carving of whose roof is scarcely surpassed by Westminster Hall or the mausoleum of Henry VII. are striking examples of this period.

Indifferent workmanship, profusion of ornament, petty divisions of compartments, overloaded with scrolls, flowers, &c., alike characterise the decline of the art in Rome and the commencement of it in England ; but the before-mentioned reasons prevented the introduction of Classical architecture into this country, though at the same time it flourished highly in Italy under Julius II.

This leads onward to the reign of Henry VIII., in which architecture, in point of expensiveness and the intention of its patrons, flourished abundantly. Wolsey the munificent, the splendid minister of a no less splendid monarch, built and endowed magnificently. His palace at Bridewell, his restoration and additions to the episcopal palace and the cathedral at York, the gateway to the Butchery at Ipswich (a proof, among others, that he did not forget his origin or his native town) ; the repairing and beautifying the pastoral residence and parish church of Lymington, where there still exist remains of his works ; his splendid palace at Charing Cross, and his far more magnificent structure at Hampton Court, were but among a few of those belonging to this ambitious and munificent prelate. As a proof of the splendid manner of Wolsey's habits, his palace at Charing, among others, may be adduced, where, on September 7, 1515, on the occasion of his being decorated with the purple, he entertained his sovereign and consort, the Queen of Scotland, the Queen-dowager of France, the Archbishop of Canterbury, the Bishops of Winchester, Rochester and other prelates, the judges and other personages of distinction in a manner equally splendid with that described by Shakespeare. His train consisted of 800 servants and retainers, many of them knights and gentlemen, and ranked nine or ten lords in his suite. Every Sunday he resorted in the most splendid and pompous manner from his palace at Charing to the Court at Greenwich, accompanied with crosses, silver pillars, his cardinal's hat and great seal of the kingdom, with all proper accompaniments. If his external splendour was thus great, what must have been his palaces and dwellings, which were the constant resort of the nobility and gentry, both foreign and domestic, where they were received and treated in a manner worthy of a sovereign prince? Yet, according to Hollinshead, Stowe, Rymer and other historians, the most useful part of Domestic architecture, the mansions of the nobility and gentry, the houses of the tradesmen and the huts of the peasants, were everything but commodious and comfortable. Among his other occupations and designs of splendour Wolsey did not neglect utility ; he founded public lectures at Oxford on theology, civil law, physic, philosophy, mathematics, Greek, Latin and rhetoric, of which at present, as he paid the professors himself and left no endowment, no remains exist. He obtained a bull from the Pope, appointing himself visitor of all the monasteries, which he used with propriety, and put them all in a perfect state of repair, embellishing and beautifying many. Among other useful acts of this useful man to his country's arts and learning, he procured the establishment of the College of Physicians.

The king was not backward in promoting works of splendour and magnificence. Scorning the narrow accommodations and inconvenient habitations of his predecessors, he erected several noble castles and palaces, among which were Whitehall and Nonsuch, now no more ; he converted St. James's from a nunnery to a palace, and appropriated another at Dartford to a similar purpose. In this reign it is supposed the Grecian, or rather the Romanised Grecian style of architecture, was introduced into Great Britain, but still in an imperfect and impure taste, mixed promiscuously with Saxon, Gothic, Saracenic or any other style they found to their hands.

In 1525 Wolsey laid the first stone of a magnificent structure at Oxford, which he intended to erect, endow and call by the commemorative name of Cardinal College, for which purpose he procured the dissolution of the priory of St. Frideswade, at Oxford, which being surrendered to the king, he immediately bestowed it on the cardinal, for the praiseworthy purpose of building on its site, and endowing with its revenues the intended college. He soon after obtained bulls from the Pope, which were indispensable, to confirm and support the king's munificent grant ; in addition to which he also procured the dissolution of several other lesser monasteries, situate in different parts of the kingdom, and applied their revenues and possessions for the building and maintenance of his new college. These proceedings met with great censure even from the king himself, with whom he was so great a favourite, who accused him in a letter of various faults, and said the college was a cloak for covering all his mischiefs. To restore this breach the cardinal made his royal master, whose avarice, extravagance and weak points he well knew, a present of his

magnificent palace at Hampton Court, and showed him his will, wherein he had made the king his sole heir; in return for which Henry gave him his palace at Richmond for a residence.

Among other of Wolsey's architectural works may be enumerated a mint at York and another at Durham, a palace at Southwell and a monastery for Carthusian friars at Sheen, an episcopal palace at Scrooby, near York, which finding after his degradation in too bad a state to reside in, he employed 300 artificers in its reparation. Pomfret Abbey, Doncaster, and Sheffield Park found also a benefactor in Wolsey. He also founded a grammar school at Ipswich, his native town, and paid great attention to the improvement of the education of youth. The furniture and decorations of his palace at York were of the most splendid description and of an immense value; the walls of the gallery were hung with cloth of gold, embellished with silver and tissue work; he had a prodigious quantity of velvets, satins and other splendid vestments, and an almost incredible quantity of gold and silver plate.

After the disgrace of Wolsey the king followed up his new college, new founded and re-endowed it, under the name it now bears, Christchurch College. Among other large edifices constructed in this king's reign, were parts of the castle at Windsor, the mansions of Cowdry, Herstmonceaux and Penshurst, in Sussex, Holland House, Kensington, Somerset House and the Savoy Palace, London.

The succeeding reigns of Edward VI., Elizabeth and James I. add but little to a sketch of Domestic architecture. In the former monarch's reign Christ's Hospital was endowed and built. The excellency and newness of the palaces required but little beyond reparations; and the grand scale of the foreign policy of Elizabeth led her to something more than merely decorating, altering or rebuilding her residences; yet many excellent private mansions were constructed during her reign.

If the reign of Elizabeth added little to the history of Domestic architecture, that of James I. added still less. Public buildings remained much as before, both in style and size; private edifices and humbler dwellings, however, improved in comforts and convenience, but not much in style. Clumsiness of proportion and inelegance of style distinguish alike both these periods.

In the succeeding reigns there is little to gratify the searcher after generalities till the reign of the accomplished and elegant-minded Charles I., who, by a course of study improved by travel, possessed a mind alike sensible to the more tasteful avocations of life, and the more refined pleasures of a highly cultivated state of society. This reign produced a great revolution in the style of architecture in general, but more particularly in Domestic architecture. Inigo Jones flourished at this time, and first introduced into this country a pure specimen of Classical architecture.

There can be little added to the above till the Fire of London. The City, with the aid of Sir Christopher Wren, assumed a new appearance; to repeat a list of his *chef-d'œuvres* would be to recount what is known to all. But we have not as much information to guide us in forming a notion of Wren's principles of domestic as we have of his ecclesiastical architecture. All we can say is that house-builders imagined they worked after his manner when they introduced Classic details. But no style has received any permanence among us. A history of English houses would be almost equivalent to a history of architecture, for wherever work was found which appeared likely to attract for a season it has been imitated. We can easily trace changes, but what they are to lead to in Domestic architecture "no man knoweth."

TESTS OF VENTILATION.

THE summer meeting of the American Society of Heating and Ventilating Engineers has been held in Atlantic City under the presidency of Mr. W. F. Wolfe. Among the papers read was one by Mr. J. C. Northcott on "Some Accepted Tests of Ventilation." He said:—Most of the methods and instruments by which we measure the results of ventilation have come into use within a generation. They are comparatively new and to some extent defective. At the beginning of my paper I wish to remind you that we are not to abandon methods of testing because they are defective until we have found other methods that are less defective, but I think it important to recognise their shortcomings.

To discover the degree of impurity of air in occupied rooms it is usual to determine the proportion of carbonic acid gas. The excess of this gas over that which is normal to outside air in a clean locality is taken as showing the degree of impurity. For two reasons this test is only approximate.

In the first place, carbonic acid gas is not the only nor the worst poison discharged into the air of an occupied room. An eminent authority states that "a man of average weight throws off through the skin during the twenty-four hours about 18 oz. of water, 300 grs. of solid matter, and 400 grs. of carbonic acid gas." This is nearly 3 lbs. of poisonous matter discharged into the surrounding air by every vigorous adult in each twenty-four hours. But less than one-third of this is carbonic acid gas. It is well known that the solid matter of excretion in an occupied room is a most deadly poison. We have no accurate means of testing its volume, except by laborious processes in the laboratory not available or practicable for general use. A well-regulated nose is the only instrument in general use which will detect the presence of this poison. We should always remember that the well-known odour of air vitiated by a crowd does not come from carbonic acid gas, but from the crowd poison, which is represented by organic and decaying matter exhaled from the bodies of occupants. We exhale filth through every pore of the skin, and this discharge is quite as offensive and as poisonous as any other discharge from the human body. You have often remarked the pallid face, the dulled and flattened eye of a prisoner in many of our gaols—and I might also say prisoners in some of our schools. This is not so much the result of the excess of carbonic acid gas as of that other form of crowd poison. You may take a crowded schoolroom, with an ample supply of pure air through an overhead register. Now lower a window from the top. The circulation of pure air will be ample through the room, but it will be almost entirely overhead. The children sitting just below this flowing current of pure air are discharging from the lungs carbonic acid gas, while both from lungs and skin they are discharging organic matter. Much of the carbonic acid gas is discharged upon the air at a temperature of about 92 degrees. The organic matter—most of it—is not so warm. It is also heavier. Impelled by the breath, the carbonic acid gas will at first ascend because warmer than the stratum of air into which it is breathed. Most of it will be caught in the outgoing currents above the heads of the children, and thus be carried away through the open window, while most of the other form of crowd poison—and the deadlier form—will, because cooler and heavier, remain in the lower and occupied stratum of air. Now, let the experimenter come into this room and test that stratum of air in which the children are sitting. He will find it comparatively free from excess of carbonic acid gas. If he is unwise, he will announce the conclusion that the air which the children are breathing is comparatively pure. But it will be a mistake. I have often heard it remarked that men who work with carbonic acid gas (as it is used in some of the arts) do not show the ill effects which we would suppose. The reason is that an excess of carbonic acid gas is not the most deadly poison of vitiated air. Yet I concede that the test for carbonic acid gas in vitiated air is, under carefully guarded circumstances, approximately correct, and, if rightly used, is of great value. This is true because an excess of carbonic acid gas is ordinarily a close companion of all other forms of crowd poison. Its presence indicates the presence of its ally.

The lime-water test aims to determine the presence of carbonic acid gas. It does not, except by inference, determine the presence of other forms of crowd poison. It is not necessary that I attempt to describe the lime-water test other than in a general way. It depends upon the fact that carbonic acid gas, passed into and through lime-water, will precipitate the lime in the water, making the water, which was at first absolutely clear, to be more or less clouded and dense with chalky matter. The amount of carbonic acid gas discharged through the water determines the degree of density.

With the Wolpert air-tester, for example, you are to determine the volume of carbonic acid gas that is passed through the water by the number of times you have discharged a bulb full of contaminated air through the lime-water before the water becomes so dense that a black spot at the bottom is obscured. Now it is evident that the experimenter may or may not exhaust the bulb or air-pump to the last degree at each filling. He may or may not inadvertently fill the bulb from that limited area of air immediately surrounding his own head, and into which he has just that instant discharged the contents of his own heated lungs.

Again, to determine when the black spot can no longer be seen through the lime-water is a question of vision. It might be obscured to me, while you, with better eyes, can still see it. Every one who has made use of this test knows how difficult it is to be quite sure when the vanishing point is reached.

The anemometer is the most useful instrument in determining the results of ventilation. It should be delicately adjusted and carefully kept so. We should remember that ventilation is, more than anything else, dilution, and so after all the best test of adequate ventilation is the anemometer test. And yet the anemometer, even if a good one, in the hands of an inexperienced or injudicious person is an unscrupulous liar. Let me illustrate. You may take a box or room through which you shall flow a given volume of air. We will suppose that the air is being discharged at the rate of 400 cubic feet per minute. Now, if the exhaust—at the floor, for example—be 144 inches long and 1 inch high, and if the air is flowing at a velocity of 400 feet per minute, you will

maintain the conditions of our problem. We will suppose that the air meter has a wheel 3 inches in diameter. You may set this anemometer in this shallow current and it will not serve to measure the outflowing air, simply because the current is not deep enough to attack the screw and impel the wheel. If now, without otherwise changing your box or room, you shall close up the long shallow opening and make another opening 12 inches high and 12 inches wide, the area at the discharge will still be maintained. The former velocity being also maintained, the discharge will again be 400 cubic feet per minute. Now put your anemometer in this current and (making the proper correction for friction) it will register with fidelity.

The case I have supposed is an extreme one, yet we many times approach such conditions or similar conditions in actual work.

So we come again to the fact that the results of even this best instrument we know, the air-meter, may be only approximate, and it is clear that in the hands of an inexperienced person it may be of little value.

I conclude as I began. We must continue to use tests which we recognise as in some measure defective. We continue to use them because they are the best known. We shall be careful, however, to make these tests with a full knowledge of their shortcomings, and a disposition to carefully watch for every affecting circumstance. In the meantime we will urge invention to find better instruments for our purpose.

Mr. W. McMannis said he depended upon the anemometer to determine the degree of ventilation obtained in the New York schools.

Mr. S. A. Jellett said that even at the best the results obtained from anemometers were only an approximation.

SECURITY AGAINST FIRE.

THE latest publication of the British Fire Prevention Committee is a paper entitled "Lessons from Fire and Panic," which was read by Mr. Thomas Blashill before the Surveyors' Institute.

The party wall as a separation between buildings is, I think, effectual if no illegal openings are made in it. Whether or not it need be carried up through the roof has been a question, but no satisfactory evidence seems to be forthcoming as to the stoppage of fire by party-walls that are not so carried up. When the London Building Bill of 1893 was before Parliament, the committee took a great interest in this question, and decided that the old height of 15 inches above the roof should be raised in the case of a warehouse to 3 feet.

As to openings in external walls where the streets or back areas are narrow, we want shutters that will delay the passage of fire from without, if only for half an hour, and will obstruct the passage of fire from within. It may be that fire-resisting blinds occupying little space will be found useful. The common lighting areas are formed by what are supposed to be external walls, and the provision of shutters or blinds to the openings in them is even more necessary. Every contrivance of this kind should be easily closed, and should be actually closed every night.

I am quite unable to understand the slow progress made in this country by the fire-resisting floor. In Paris fire-resisting floors were common five-and-thirty years ago. I was then carrying out such work here on a large scale, but the case was exceptional; the weight of the floors was great, the walls had to be thickened, and the cost was excessive. Cheap steel and light substitutes for concrete have changed all that.

In the Cripplegate fire, although many of the warehouses were modern, and some had already been burnt out once or oftener, there was not a single fire-resisting floor. There were wooden floors carried on iron girders, but we are familiar with the behaviour of wrought-iron girders under such conditions. They expand and contract so as to overthrow the walls, or they become soft so as to hang down like tapes. There are now available fire-resisting floors in great variety in which the iron is more or less protected from the fire. In using them care must, however, be taken that no leakage of gas can accumulate in any hollow spaces. I have seen a large and handsomely decorated house in which fire-resisting floors were used in conjunction with battened walls. Upon applying a light in the usual way to the suspected point of escape the mixture of gas and air accumulated in the hollows exploded, and the ceiling with the wall battening in two storeys was stripped away, littering the floors and mixing with the broken window glass. In that case there were also severe personal injuries.

In the great re-housing schemes of the London County Council I have made every floor fire-resisting by the use of steel joists wide-spaced, and filled in solid with coke breeze concrete upon which the floor-boards are nailed, the plastered ceiling being done under the concrete direct. The cost is no more than that of a good wooden floor, while the tota thickness is only 7 inches, which saves 2 or 3 inches in the height of each storey. They are not complained of by the tenants in respect of noise, but in a house where this would be of great consequence a cork covering to the boards under the carpet would be a sufficient remedy.

If it is necessary to adopt wooden construction for floors, the ordinary pugging should at least be used. Joists of double the usual thickness placed 2 feet apart and filled in solid with some form of concrete, would offer great resistance to fire. As to the material for pugging, coke breeze and cement concrete, mixed four parts to one, stands fire and water better than anything else. In Switzerland they use coarse plaster stuff, into which long wet shavings have been stirred as hair is stirred into plaster for ceilings; and this, though an imperfect substitute for concrete, will resist a fierce fire for a considerable time, but more experience is required in the use of light solid materials.

I think we have now arrived at a time when architects should at least try to secure an incombustible roof. This is stipulated in the building leases of some very important London estates, and I am told that it raises no difficulty. If the space in the roof is wanted, pugging or concrete is sometimes put between wooden rafters. If a steep roof is necessary, sheets of asbestos put on the roof boarding in place of felt will afford some protection. In a building professing to any degree of fire resistance, the roof should be protected by a ceiling of concrete put over the topmost storey. Ceiling on perforated or expanded metal will give some protection against a small fire.

As to partitions, lath and plaster should be quite abandoned, and brick-nogging also, for a half-brick wall in cement is as easily constructed. There are many kinds of thin partitions from which to choose. I commonly use coke breeze cement concrete 2 inches in thickness, which is light, tough and strong enough for storeys of the ordinary height. Old lath-and-plaster partitions may be filled in with this material or with brickwork by removing the plaster from one side only. If the structure is otherwise fire-resisting, any wooden panelled partitions may be considered as fixtures and disregarded, particularly if in hard wood.

I mention these and similar details, not as being unknown, but as being too often neglected, even where the cost would not be a serious item. If fire-resisting materials were in more regular demand workmen would become familiar with them and they would cost less. Exaggerated estimates of the cost of fire-resisting construction do much harm. Very important steps can certainly be taken in that direction with very little extra cost on ordinary construction.

The great danger of a staircase arises from the cupboard underneath its lower flight, which will probably be stored with combustible materials. If it is constructed of thin deal it will take fire easily. If more solid or made of hard wood it will resist a small fire for some time. If it is to be fire-resisting, concrete is better than stone. But if everything about a staircase is incombustible it may be rendered useless by accumulated smoke arising from such a cupboard as I have mentioned, or from an adjoining room.

There are certain precautions necessary in construction whether the materials are fire-resisting or not. I have already suggested the danger of hollow floors and hollow partitions, but all hollow spaces that can contain gas or transmit flame or inflammable vapour, or will even allow a supply of air to pass towards a fire, are highly dangerous. The lining of walls with matchboarding is the most ordinary case of this kind. By means of it fire communicates instantly all over a shop and up through the floor to the rooms above. The hollows formed in heavy plaster cornices and the hollow spaces behind skirtings transmit flame or inflammable air without any outward warning to adjoining or even distant rooms. One instance or two will illustrate this.

In a fire near Clapham Junction that originated among the Christmas decorations in a draper's window the smoke and flames passed in this way to the upper floor so quickly that two girls at work over the back part of the shop lost their lives, although there was an easy means of escape by getting out of the back window on to a flat. In a similar case several persons, probably seized with panic, jumped from first-floor windows into the street, instead of stepping out at the back. These are indications of the quick effect of fire in a badly-constructed building.

As to the passage of fire or inflammable vapour by hollow spaces, cases have happened where the origin of a considerable fire was inexplicable until it was traced back to some source at a considerable distance from the scene of the damage. In a "fireproof" building a workman hung his coat in a cupboard leaving his pipe in the pocket. The coat took fire and fell, setting light to the skirting, behind which a small hole had been left in the brick internal wall. The floor boards of the adjoining room had been laid on wooden strips that stood above the surface of the concrete. The fire passed along the hollow space, doing 3,000*l.* worth of damage in this "fire-

proof" building. Unless the elasticity of a floor is an object the board should be nailed down on to a surface of coke breeze concrete.

If no more serious measures than those I have described are taken in respect of a purely domestic building, they may give very material security as to its behaviour in case of fire. For many years past companies have been erecting artisans' dwellings in London, one of them having put up blocks containing nearly 6,000 tenements. In only one case has a fire in any artisans' block extended from one tenement to another. This is due to generally careful construction, though there has been no rigid adherence to fire-resisting principles.

In these descriptions of the parts of a fire-resisting building the work of the carpenter is practically excluded, and there are many buildings in which this principle should be carried out. There is, however, much convenience in the use of timber, and if posts and girders are made in large sizes, they are safer than if made in iron. Solid floors made of deal joists set close together withstand fire for a long time, but are ultimately destroyed by great heat.

Many attempts have been made to render fir timber fire-resisting or slow-burning by chemical treatment or by covering it with paint. Some of these applications are useful when applied to textile fabrics and to thin slips of wood, but I have been unable to meet with any process that renders the mass of a joist or beam fire-resisting throughout. This is a matter well worth further inquiry and experiment, for joinery at least might be protected in this way. As to the public experiments sometimes reported, those in which tar or mineral oils are liberally used are untrustworthy, for these are light-giving and smoke-producing liquids, and do not imitate the conditions of an ordinary fire.

Although we may succeed in rendering new buildings satisfactorily fire-resisting, a much more important question for the present generation is the improvement of the condition of old buildings. This is well worth the attention, of those who have the charge of building estates already covered, of ordinary town property, or of those old historic mansions filled with family treasures, one of which as I write has been added to the number of those wrecked by fire. In an ordinary building, purely domestic, if the joists are not strong enough to carry a filling in of concrete they will carry ordinary pugging, and if no more than a breadth of 3 or 4 feet all round a floor is well filled in on some fire-resisting system, every hollow behind adjacent cornices, skirtings and partitions being carefully stopped, a very considerable amount of resistance to fire will be afforded. If, besides, the points of contact between chimney stacks and floors and roofs be examined and timber cut away, the condition of an old house might be made approximately as good as that of a new building. In certain cases, where in London a domestic building is changed into a public building, and where a building partly domestic and partly used for trade is increased in area, something of this kind has now to be done.

Even more important than these details of construction is the question of arrangement of buildings with the view of preventing loss of life from fire. Warned by frequent disasters, the legislature has from time to time made provision for protecting persons from sudden fire and panic, and for insuring to the inmates of certain buildings reasonable means of escape.

Examination of this kind must be thorough, for it is difficult to exhaust the possibility of mischief caused by careless workmen in old or in modern times. I have found in an old house the brickwork of a chimney breast cut away to enlarge a cupboard, a thin board being substituted, which had evidently done duty for years in that position.

And with regard to any building the architect cannot be too cautious against assuming that reasonable care will be taken in managing it. Most houses are at times, often for a very long time, left in the hands of people without sense of responsibility. That is an additional reason for making every structural provision against the chance of a fire.

The London Building Act, 1894, provides by section 61 that every building over 30 feet in height used wholly or in part as a dwelling-house or factory, and having a parapet, shall have a dormer window or door opening on to the roof, or a trap-door with a fixed or hinged step-ladder leading to the roof, or with other proper means of escape. If there happens to be no parapet there is no such provision. I venture to think that it would only be ordinary prudence to make this provision in any house or factory where there is reasonable doubt as to the means of escape by the ordinary route. Section 62 partially meets this view by requiring that any storey in the roof, the floor of which is over 60 feet above the street, shall be constructed of fire-resisting materials, and section 63 provides that every building over 60 feet high shall have on the storeys, where the floors are over 60 feet above the street, "such means of escape in the case of fire for the persons dwelling or employed therein as can be reasonably required in the circumstances of each case." No such storeys can be occupied until the London County Council certifies that this has been done. This is new legislation, and it has now become a very important part of the duty of the Council to say what can be reasonably required in such cases.

The height of 60 feet is fixed because that is the greatest height to which a movable fire-escape will reach, and without some special provision the only means of escape from these high storeys would be by descending, if that were possible, to the lower storeys, and increasing the number of persons there in peril. Schemes to be applied to lofty hotels and houses more or less crowded at night have come before me in great variety, many of these very inadequate. It seems clear that the law, which leaves the occupiers of floors up to 60 feet in height to take their chance, intends that those on higher floors shall escape. They may have a gallery or an iron ladder or staircase for access to the roof of an adjoining building, or a series of ladders may be contrived that will conduct them clear of the windows of the burning building down to the ground. But 60 feet is a great height from which to expect women, children and sick persons, scantily dressed, suddenly alarmed in the night, and for the first time in their lives, to descend by an external ladder, in any weather and probably in the dark. They must be of tolerably good slope, have flat treads and hand-rails, and there must be suitable protection where necessary against falling into areas or through skylights. The escape door must have such fastenings only as can be easily opened from within. It must be easily found by night, and the bottom of the escape must be in some open space quite clear of danger. But whether the escape delivers to the ground or on to some willing neighbour's roof, there is risk that it will be made use of by burglars and by inmates of both premises for improper purposes. If a separate staircase leading down to a separate door of exit is provided in the building, it will very likely be allowed to go out of use, and will be turned into a store place for lumber. On the other hand, if the construction of dwelling-rooms above the 60 feet limit is of very great consequence, the owner may reasonably be required to make and keep up such arrangements, however costly, as will be really efficient.

By the 74th section of the London Building Act, when a building over 1,000 feet in area is used in part for purpose of trade and manufacture, and in part as a dwelling-house, the two parts must be separated by walls and floors of fire-resisting materials, and all means of approach to the dwelling-house portion must be constructed throughout of fire-resisting material. But the walls of staircases and passages may have openings fitted with fire-resisting doors to communicate between the two portions, for which purpose hard wood 2 inches thick is reckoned fire-resisting. For staircases hard wood 2 inches thick is also permitted, and good concrete when filled in between the joists of floors is fire-resisting.

It will be observed that the term "fire-resisting" is used and not "fireproof." The construction must not add fuel to the fire, but resist it for at least a considerable time, during which the inmates of a building may escape and fire appliances be brought to bear. If the contents of the room or even of the building cannot be saved, so much the worse for the owner or the insurance company; but the fire should rarely extend to the adjoining apartment on either side or to a storey above or below, and the smoke should be kept from staircases and passages. This means giving to adjoining sections of a house as nearly as practicable the same protection against each other as a good party wall affords to the inhabitants of an adjoining house.

THE MICROSCOPE AND ROCK STUDIES.

FROM time to time within the last few years many applications have been made by teachers, students and other visitors to the Museum of Practical Geology, London, for permission to examine thin sections of rocks under the microscope. As it would interfere with the work of the Geological Survey to allow strangers to study in the Petrographical Department, and it would obviously be unsafe to entrust them with the use of valuable instruments, a small strong microscope of special construction has recently been acquired and set apart for the use of visitors. Twelve typical rock sections have been mounted on a revolving stage, where they are fixed in position and protected by a thick glass plate so as to avoid any chance of injury by those who are not familiar with the manipulation of a microscope. The instrument is provided with a one-inch object-glass and with polarising apparatus. The sections selected by Mr. W. W. Watts comprise examples of pitchstone, rhyolite, granophyre, granite, trachyte, angite-andesite, hornblende-diorite, olivine-basalt, ophitic dolerite, phonolite and leucite-rock. Coloured sketches of these sections as viewed under the one-inch objective have been carefully prepared by Mr. Gilbert Williams, and are accompanied by short descriptions written by Mr. Watts. As it would be hardly safe to place the microscrope in a public museum for indiscriminate use, it is at present kept in the library, where it may be used by visitors on application.

THE FUTURE OF LORD LEIGHTON'S HOUSE.

THE interesting collection of sketches and studies which for the last two months has been undergoing an intermittent private view at the house of the late Lord Leighton raises in an acute form, says the *Times*, the question of the future of both the house and the sketches. There is a fitness about the present arrangement which is beyond dispute. The untiring industry of the artist, his exquisite sense of form, are illustrated even more forcibly by the introduction to his studio than by an exhibition of his finished works. Pencil drawings dating from Italian days—some wide-stretching landscape, a classic building, a quaint group—marvellous delineations of the endless complexity of a great tree, almost anatomical studies of every figure—almost every limb of every figure—which finds a place in one of his great pictures, all combine to prove the unerring accuracy of eye and hand, and the ceaseless pursuit of perfection which characterised the man, who would never sign a picture, lest it should be taken to indicate that he was satisfied with his work. Such a collection is not only of high interest to the layman, but of exceptional educational value to the student. It might, no doubt, properly find a place in one of the large national galleries or museums, there to be overlooked among more obvious achievements, perhaps to be hidden away in drawers and cupboards, and produced on rare occasions to the exceptionally curious. But at present it has its appropriate setting in the very workshop where much of it was created. And how characteristic a setting. In Germany a great man's Geburtshaus or Wohnhaus is held sacred, though not in itself of any beauty. Thomas Carlyle's house is interesting only for its associations. But Leighton's house is as much one of his works as the Daphnephoria or the Arts of Peace. It was built to his designs, it has a suite of ideal studios, it is protected by a sufficient and pleasant garden; its floors, its walls, its staircase are rich with the marbles, the paintings, the tiles, which satisfied the artist's taste; and as an adjunct to its living-rooms it possesses the well-known Arab Hall. This suggestion of the East was Lord Leighton's own creation. Having the good fortune to acquire an unusually large number of fine Persian tiles, he endeavoured to give them a congruous home. Marble columns designed by Boehm, a frieze in which Mr. Walter Crane's fancy finds play, Cairene woodwork and Syrian glass are brought together in a lofty vaulted chamber, the walls of which are lined with the precious pottery. The splash of a small fountain invites to day-dreams, while the eye runs riot over the blues and greens and lilacs of the tiles, the gold of frieze and capitals and the warm tints of the Damascus glass. Such a profusion of rich and varied colouring in internal decoration it would be difficult to match.

By what means, then, can house and sketches be preserved in their present happy union? It is well known that Lord Leighton left his house absolutely to his two sisters. These ladies, with a munificence which recalls their distinguished brother, have now, by way of gift, transferred the property to representatives of the committee which has, ever since Lord Leighton's death, kept alive the hopes of the eventual preservation of the house. They have done more. They have by liberal gifts aided in rescuing from dispersion the interesting collection which now finds a home in the house. A large circle of friends and admirers of the artist (headed by the Prince of Wales) have contributed to the same end by purchasing sketches from the Fine Art Society (to which they were entrusted for sale) and presenting them to the house. Thus at the present moment both house and sketches are in the hands of those whose one desire is to make them the permanent possession of the nation. But to achieve this object something more is needful. Lord Leighton's house was not his freehold. It is held from Lord Ilchester under leases carrying substantial ground rents. The lighting, the water supply of the house—to say nothing of possible contributions to rates and taxes—its repair and maintenance, and the provision of proper caretaking represent not a large but a very appreciable annual expenditure. A mere voluntary committee—still less two or three private persons—cannot be expected to hold for an indefinite period a property entailing liabilities. In the form of annual subscription, guarantee, or endowment some means must be found of meeting current outgoings; and somebody of a permanent character to hold and manage the house must be brought on the scene. There should be no great difficulty in complying with either condition. The Vestry and the Library Commissioners of Kensington have shown a keen interest in the preservation of the house. Under the Public Libraries Act the commissioners have power to provide not merely public libraries but "art galleries" and "schools for art," and in the administration of such places they have a free hand. Lord Leighton's house might be made a "school for art" in the widest sense. Not only should students of form and composition have full opportunity for the examination of his work and methods. The large studio forms an admirable room for lectures, for chamber music, for representations of the higher forms of drama. One can imagine that under skilful management such a place, starting with the invaluable endowment of association with a gifted and winning personality, might be made a living agency for the education of the eye and ear in the appreciation of beauty of form, of colour, of sound. And in so doing the house and its contents might to some extent provide for their own maintenance. Certain difficulties incident to a leasehold tenure have to be overcome, but Lord Ilchester, as ground landlord, has shown every inclination to facilitate the objects of the committee. It rests with Kensington first, and in the second place with the nation, to decide whether the brilliant President of the Academy shall be commemorated in the way which would have been most to his wish, by the consecration of his house and its drawings to the advancement of art, and the gladdening and refining of the national life.

THE OLD WINDOW TAX.

DIRECT taxes may be a necessity, but they were never popular in England. It is also found that they press unequally. But they have the advantage for collectors of being difficult to evade. Hence it was that from time to time houses or parts of houses, such as windows, chimneys, hearths, &c., were selected as subjects for taxation. Macaulay says that under Charles II. the tax on chimneys was, even among direct imposts, particularly odious, for it could be levied only by means of domiciliary visits; and of such visits the English have always been impatient to a degree which the people of other countries can but faintly conceive. The poorer householders were frequently unable to pay their hearth money to the day. When this happened their furniture was distrained without mercy, for the tax was farmed, and a farmer of taxes is, of all creditors, proverbially the most rapacious. The collectors were loudly accused of performing their unpopular duty with harshness and insolence. It was said that as soon as they appeared at the threshold of a cottage the children began to wail and the old women ran to hide their earthenware. Nay, the single bed of a poor family had sometimes been carried away and sold. The net annual receipt from this tax was 200,000*l*. The abuses of collection caused many changes, and a house tax which could be assessed without passing a threshold was levied. The necessities of the State afterwards imposed a tax on windows in addition to houses. Then the house tax was removed, partly because it was supposed to discourage the occupation of houses, but the window-tax duty was retained.

The duty on windows was not favourable to the provisions for admitting daylight into houses. It was found that in many cases window openings were blocked up in order to evade the payment of the duty. In new buildings, although the positions of the windows were arranged, glass was not introduced. The size of windows was also restricted. The Act 48 Geo. III. cap. 55 was passed in order to introduce some system into the arrangements. It enacted that:—

1. All skylights, and all windows in staircases, garrets, cellars, passages and all other parts of houses, to whatever use applied, were subject to the duties.

2. Every window in any kitchen, cellar, scullery, buttery, pantry, larder, washhouse, laundry, bakehouse, brewhouse or lodging room belonging to or occupied with any dwelling-house, whether the same was within or contiguous to or disjoined from the body of the dwelling-house, was also subject to the duties.

3. The duties were to be charged annually upon the occupier, his executors or administrators.

4. When any change in the occupation took place after the assessment, then the duties charged on the former occupier were to be paid by the present occupier, landlord or owner of the premises, without any new assessment, notwithstanding such change in occupation. But where a tenant left, and gave notice thereof to the assessor, the duty was discharged for the remainder of that year, provided it appeared to the commissioners that the premises continued wholly unoccupied.

5. Where a dwelling-house was let in different apartments, it was to be charged as if let to one person only, and the landlord or owner was deemed the occupier and charged. But in cases where the landlord did not reside within the limits of the collector, or the duties remained unpaid by the landlord for twenty days after they were due, they could then be levied on the occupiers, and the amount deducted out of the next rent.

6. Every house that was left to the care of any person was equally subject to the duties, which were to be paid by the owners or tenants.

7. Every window, including the frame, which by admeasurement of the whole space of the aperture on the outside of the wall exceeded in height 12 feet, or in breadth 4 feet 9 inches (not being less than 3 feet 6 inches high), was charged as two windows, except those that were made of greater dimensions prior to April 5, 1785; and also the windows in shops, work-

shops and warehouses, and the windows in public rooms of any house licensed to sell wine, ale or other liquors for the entertainment of company, and the windows of farmhouses especially exempted from the duty on houses.

8. Every window extending so as to give light into more rooms, landings or storeys than one was charged as so many separate windows, as there were rooms, landings, or storeys so enlightened.

9. When a partition or division between two or more windows fixed in one frame was of the width of 12 inches, the window on each side was charged as a distinct window.

The only exemptions were houses belonging to the king or any of the royal family, public offices, hospitals, charity schools and poor-houses, except such apartments as were occupied by the officers and servants, which were assessed as separate dwelling-houses; the windows in any room licensed for divine worship, and used for no other purpose; and the windows of dairy and cheese-rooms, made of splines or wooden laths or iron bars, and wholly without glass.

The amount of duty was 6*s.* 6*d.* for every house which had no more than six windows, and of a rental of less than 5*l.* a year; if worth 5*l.* the duty was 8*s.* For houses worth more than 5*l.* a year the duty was charged by the number of windows. The amount varied for every window. For a house with seven windows the duty was 1*l.*, but for nine windows it was 2*l.* 2*s.* A house with fourteen windows paid 6*l.* 3*s.* 6*d.* On one with twenty-eight the duty levied was 17*l.* 19*s.*, while one with fifty-six windows paid 37*l.* 6*s.* The occupant of a house which had twenty windows paid 11*l.* 4*s.* 6*d.*, while for thirty windows the sum was 19*l.* 12*s.* 6*d.*, for forty windows 28*l.* 17*s.* 6*d.*, and for 100 windows 58*l.* 17*s.* The highest number specified was 180 windows, the duty on which was 93*l.* 2*s.* 6*d.* If there were more the additional windows were charged 3*s.* each.

TESSERÆ.

Hieroglyphical Writing.

THERE are three species of Egyptian writing. The first is that of the temples and tombs, in which all the symbols used to appear in their complete forms, well defined and often carefully coloured so that the objects intended to be represented can be in general clearly recognised. This is the style to which the name hieroglyphics is primarily applied. It is employed in many of the funereal papyri or rituals, which were wont to be buried with the dead, the forms of the objects being drawn in outline, with slight modifications according to the taste of the scribe and for the sake of speed in writing. The next species is that termed hieratic, which is a modification of the preceding, and was used for literary compositions and the purposes of ordinary life. Funeral rituals were also not infrequently written in this character. The forms of many of the hieroglyphics are so much altered in this style that it would be impossible to recognise them except by a comparison of identical passages written in both characters, which the hieratic rituals fortunately enable us to effect. The hieratic may be broadly described as the cursive writing in general use in Egypt from the earliest period down to about 600 B.C., or nearly to the time of the Persian invasion. During this long period several varieties of it occur, but the writing is essentially the same. About 600 B.C. it began to be supplanted by the third species, called by the Greeks demotic, which is an abbreviated and less cumbrous form of the hieratic. The principle of all these three kinds of writing is the same. In general each word is spelt by phonetic signs, which stand either for letters or syllables. The word thus spelt is followed by one or more symbols, which are not sounded, but indicate the class of ideas to which the word belongs. Thus there are symbols to mark ideas of motion, violent action, repose, thought, wickedness, animals, vegetables, and a host of others. This ingenious combination of symbolical and phonetic writing has been the means of preserving the Egyptian language to us, for without the hints afforded by these significant characters the task of interpretation would be almost hopeless.

Sites of Greek Theatres.

A proof of the Greek love and admiration of beautiful scenery is often derived from the situation of their theatres, many of which, as those of Argos, Syracuse, Tauromenium and the Dionysiac Theatre at Athens, in their present ruinous condition, now that only the seats cut in the rock for the spectators remain, certainly do command the most lovely prospects. But those who use this argument appear to do what certainly the spectators could not have done—to overlook, namely, the stage wall, which, when standing, would most effectually have shut out all view of anything beyond the stage from all but the occupants of the very highest rows of seats. Indeed, if we may draw an inference as to the ordinary height of these appendages to the theatres from the enormous pile of masonry, 100 feet high, which composes the stage wall of the theatre at Orange, no single spectator in the theatre was in danger of having his attention diverted from what was passing on the stage before him by the attractions of the distant prospect. In any case the motive assigned could not in any degree have influenced their choice of a site for their theatres, and we are forced to fall back upon that which was, after all, probably their sole reason for the selection—the convenience offered by a sloping rock, which in a country like Greece must always have been sufficiently near at hand for the construction of the immense extent of semicircular benches which were required for the national exhibitions and assemblies which took place in these buildings.

Parmigiano's "St. Jerome."

An anecdote related by the Padre Affò is a modern counterpart to more than one classic story of the kind, resembling more particularly that of the painter Protogenes, who, we are told, pursued his occupation in tranquillity while Rhodes was stormed by Demetrius Poliorcetes. "Parmigiano was earnestly engaged in giving the last touches to the picture of *St. Jerome* for La Buffalina when, the walls of Rome having been scaled and the city itself taken by the invaders, the wild soldiery ran from house to house intent on spoil. The painter, absorbed in his occupation, paid no attention to the roar of the artillery, the tumult of the people or the shouts of the military, till some of the enemy, rushing into the very house and searching every corner, suddenly entered the room where the artist was at work. The amazement of the soldiers on seeing him thus quietly pursuing his labours was greater than his own on finding himself surrounded by lawless and hostile men. Fortunately the leader of the band, who had meanwhile taken possession of the house, happened to be an amateur of painting. He felt an interest for the artist, and contented himself by only requiring him to execute a good number of drawings." The painting of the *Vision of St. Jerome* was to be placed in the family chapel of Maria Buffalina, in the church of San Salvatore di Lauro, at Città di Castello. It remained there till 1780, when the church of San Salvatore was ruined by an earthquake, and the picture was purchased by an English collector and brought to this country. After passing through different hands, it was finally purchased by the Governors of the British Institution, at the sale of Mr. G. Watson Taylor's pictures in 1826, and by them presented to the National Gallery.

Ancient Vase Production.

If we consider the regular and organic development in the art of vase-painting, and the resemblance among the vases found in the most distant parts of the ancient world, we feel inclined to look to one particular place or country in which they originated, and in which the art was developed. If, in addition to this, we remember that the subjects represented on these vases, as far as they are intelligible to us, belong to the mythical history of Attica, and that the characters in the inscriptions underwent, in the period in which the vases were manufactured, the same changes as those which we find in Attic inscriptions, together with various other circumstances which are carefully weighed and examined in the work of Kramer, we can scarcely doubt that Athens was the place where they were manufactured, and from whence they were exported to various other parts of the ancient world. Some of the vases belonging to the first class, especially those with Doric characters in their inscriptions, may have been made at Corinth. The principal manufactory at Athens seems to have been in the Ceramicus, a suburb of Athens. The trade which Athens thus carried on in painted vases must have been very extensive. Other towns, too, as we know from Pliny, who speaks only of his own time, had their potteries, in which vessels of various kinds, and some of great beauty, were manufactured for the purposes of ordinary life, and an extensive trade in them was carried on.

Treasure Trove.

The Roman civil law gave treasure found in general to the finder; but if found accidentally in another man's land, half was given to the finder and half to the owner of the land. And so if it was found in the land of the emperor, it was to be equally divided between him and the finder. Grotius says that the title of the prince to treasure trove had in modern times been so generally established in Europe as to have become "jus commune et quasi gentium." The law of England adopts the definition of treasure trove from the civilians as "vetus depositio pecuniæ cujus dominus ignoratur;" and to entitle the Crown to the property it must appear to have been hidden or deposited by some one who at the time had the intention of reclaiming it. Whenever, therefore, the intention to abandon appears from the circumstances—as for instance, where the property has been found in the sea, or in a pond or river, or even openly placed upon the surface of the earth—it belongs to the finder. In England the concealment of treasure trove from the king was formerly a capital offence. By the law of England treasure trove is a branch of the revenue of the Crown. Where

coin, plate, or precious metals are found hidden in the earth or any private place, and the owner or person who deposited them is unknown, the property becomes vested in the king by virtue of his prerogative. But if the owner is known, or is ascertained after the treasure is found, the property belongs to him, and not to the Crown.

Perspective in Painting.

The business of perspective is to represent objects as they appear to the eye, or as they are delineated on a transparent plane placed between the spectator and the object. The rules of perspective, as well as other rules, may be injudiciously applied, and it must be acknowledged that a misapplication of them is but too frequently found even in the works of the most considerable artists. It is not uncommon to see a figure on the foreground represented near twice the size of another which is supposed to be removed but a few feet behind it; this, though true according to rule, will appear monstrous. This error proceeds from placing the point of distance too near the point of sight, by which means the diminution of objects is so sudden as to appear unnatural, unless you stand so near the picture as the point of distance requires, which would be too near for the eye to comprehend the whole picture; whereas, if the point of distance is removed so far as the spectator may be supposed to stand in order to see commodiously, and take within his view the whole, the figures behind would then suffer under no such violent diminution. Du Piles gives an instance which proves, as he imagines, the uncertainty of the art. He supposes it employed to delineate the Trajan Pillar, the figures on which being, as he says, larger at the top than the bottom, would counteract the effects of perspective. The folly of this needs no comment, and it is not true, the figures on that pillar being all of the same dimensions.

Memorial Columns.

The idea of employing a column for a public memorial was probably derived from Egyptian obelisks. It seems to have been first adopted by the Romans, but neither manifests much invention nor regard to propriety. An obelisk is evidently complete in itself; is not intended to bear any support or to be kept steady by it, but is calculated to stand by itself. A column, on the contrary, is only a member of a structure, detached from which and from its entablature it has no meaning nor any particular grace, being apt to look tottering and "top-heavy." It is chiefly as forming a lofty and conspicuous object that a single colossal column recommends itself as a triumphal monument, yet such general outline might be preserved without adhering to the precise shape and details derived from examples from any one of the Orders. In this respect Trajan's Pillar is not so great an architectural solecism as many of the numerous columns professing to be in imitation of, or "after" it, because, owing to its shaft being entirely embossed with sculptures, the ordinary column character is done away with, and a degree of variety and magnificence is produced which may be allowed to silence the objections of criticism. There certainly was something poetical in the idea of making the shaft which bore the emperor's statue record his conquests and military exploits; and the sculptures themselves are not only superior specimens of Roman art, but highly interesting and valuable as historical documents of costume. At the same time they serve to make evident how very ill the surface to which they are applied is calculated to display them; for, instead of being extended horizontally, this vast bas-relief is coiled spirally from the base to the summit, so that the figures on the upper part of the shaft can hardly be made out, nor can those on the lower one be viewed consecutively without going round and round the column. This historical poem, as it has been called, addresses itself therefore more to the imagination than to actual inspection.

Invention in Art

As regards the operations of the mind which are employed in the process of imagination, and of invention also, these are of a twofold nature, the first of them consisting in the combination of ideas one with another. Through the instrumentality of this combination, ideas of different kinds are joined together and blended into one, forming by this means an original compound idea or object wholly different from either of those out of which it was constituted, and appearing to the mind as though an entirely and absolutely new creation has been effected, in its nature and properties in all respects varying from any of those which separately contribute to its constitution. Thus, in an analogous manner, in chemical science water is compounded of certain gases or elements, each of which in its separate state has no apparent affinity or resemblance to the production which their union together serves to originate. It is obviously of the very highest importance that the combinations which the mind makes for this purpose, and by which all imaginative ideas are generated, should be carried out in a manner suitable to this end, and should, as far as requisite, be regulated by the principles laid down with respect to artistical design and composition in general. Thus the ideas which are so combined should be those only which would be naturally brought together and united in one object, and not such as we should never see in nature so conjoined. These ideas should also be such as will not only blend together, but such as will, as it were, melt down and amalgamate into one entire and single whole. Moreover, although the combinations which the imagination effects are all the result of art, yet nature should never be lost sight of in the mode of making them; and from her alone should all the materials for combination be drawn, which should, although combined, still appear as in their original state. The combinations should also be as natural as regards the mode of effecting this operation as are the elements of combination themselves. Indeed, all imaginative and inventive efforts, in order to be sterling and durable, must be founded in nature. This is the only metal which will pass current in all ages and in all climes; and in the highest flights of the imagination nature should be regarded as the ground on which we must eventually alight. This rule, moreover, holds good in invention as well as in imagination.

Foot Rules.

In the ruins of Herculaneum a square ivory measure with the four sides smooth was found. It might be called a half-foot rule. It contained five inches, five lines, and about half a line, by the French measure. Barthélemy saw a foot rule in brass, folding together by means of a spring, a little bent, of the same admeasurement as the last. They are lineated, like modern rules, in Gruter and Montfaucon, and are probably foot rules, *i.e.* pedalia. There were also foot measures in the shape of feet. In Cicero we have the decempes, or ten-foot rule. Martial describes the quincupeda or quincupedal, a five-foot rule, as made of the wood ilex, distinguished by marks (*puncta notis*), and ending in a sharp point. He adds that it was used, as now, by surveyors to detect contractors of building.

Roman Cottages.

The Roman cottages, as they appear in paintings at Pompeii, differ only from the modern in not having transom or garret windows, and the door at the gable end. There is no chimney. The roof is coved or arched. Ovid, in his "Baucis and Philemon," amply describes the cottage, and from him we find that it was roofed with thatch of reeds or straw. The door was so low that it could only be entered by stooping. Flitches of bacon were suspended from a black beam, and dry branches for firing hoarded in the roof. A beechen vessel for washing the feet, and a bedstead with willow feet, a three-footed table, one foot unequal, olives and cornels in pickle, endive, radish and cheese with roasted eggs, occur as the furniture and fare, the latter of which is served up in earthen vessels. The table was rubbed clean with green mint. The bowl was of pottery, and the cups of beech smeared within with wax.

GENERAL.

The Burgh Engineer of Dundee has prepared plans for an extension of the Esplanade which will cost about 36,000*l.*

Mr. T. Armstrong has been allowed to remain in the service of the Science and Art Department for another year as director of art at South Kensington.

A Special General Meeting and Council meeting of the Institute of Sanitary Engineers will be held at the offices, 63 and 64 Chancery Lane, on Monday next.

The Annual Meeting of the Cambrian Archæological Association commenced at Ludlow on Tuesday under the presidency of Lord Windsor.

The Devon and Exeter Architectural Society having considered the correspondence between the architects of Plymouth and the Corporation concerning the Tavistock Road Competition, passed a resolution approving of the action of the local architects, and expressing regret that the Corporation were unable to accede to their suggestions.

The Trustees of the National Gallery have purchased (subject to the permission of the Court of Chancery), under a special grant of money from the Treasury, two pictures by Rembrandt, the property of Lady de Saumarez, entitled "The Burgomaster" and "The Burgomaster's Wife," being portraits of an elderly man and an old lady not at present identified. These pictures will be hung in the principal Dutch Room. The "Virgin of the Rocks" has been transferred from the Florentine Room to the Milanese Room, where it is now hung between the two wings by Ambrogio de Predis, recently purchased.

The late Charles Garnier was buried in the Mont Parnasse Cemetery, Paris, on Sunday. The pall-bearers were M. Bourgeois, Minister of Public Instruction; M. Larroumet, M. Francisque Sarcey, and M. Gérome. M. Larroumet delivered an address over the grave.

THE

Architect and Contract Reporter.

IMPORTANT NOTICE.

WORKMEN'S COMPENSATION ACT.

In view of the many difficulties which are certain to arise in connection with the law, practice rules and procedure under the above Act, we have added to our staff A VERY EMINENT BARRISTER, who has made the subject a special study, and will be glad to answer in the columns of this paper any questions relating to the complicated matters arising from the provisions of this difficult Act. Our LEGAL ADVISER will further answer any legal question that may be of interest to our readers. All letters must be addressed "LEGAL ADVISER," Office of "The Architect," 175 Strand, London, W.C.

EDITORIAL NOTICES.

The authors of signed articles and papers read in public must necessarily be held responsible for their contents.

No communication can be inserted unless authenticated by the name and address of the writer—not in every case for publication, but as a guarantee of good faith.

Correspondents are requested to make their communications as brief as possible. The space we can devote to Correspondence will not usually permit our inserting lengthy communications.

TENDERS, ETC.

*** *As great disappointment is frequently expressed at the non-appearance of Contracts Open, Tenders, &c., it is particularly requested that information of this description be forwarded to the Office, 175 Strand, London, W.C., not later than* 2 P.M. *on Thursdays.*

157 STRAND, W.C. (Four Doors from Somerset House), LONDON.

TRADE NOTES.

Mr. H. E. Aspinall, of "Enamel" fame, is interesting himself just now in an invention which will probably become almost as popular as the one which has converted its proprietor's name into an active verb. The invention at present in question, however, is a Venetian blind, and it is being brought out by the Adam Blind Syndicate, of 56 Cannon Street. As shown in sketch the Adam Blind presents an attractive appear-

ance. It can be painted, stained in any colour or varnished so that the original grain of the wood can be displayed. It can be ornamented to suit individual taste or any requirement of the position in which it may be desired to place it. It can only be pulled up straight, and thus obviates a prolific source of unsightliness. Among the many advantages claimed for the new blind durability, economy and cleanliness are especially insisted on, and apparently with reason.

The new Board Schools, Frinton-on-Sea, are being warmed and ventilated by means of Shorland's patent Manchester stoves, patent exhaust roof ventilators and special inlet tubes.

A large clock has just been erected in St. Margaret's Church, Leicester, by Messrs. John Smith & Sons, Midland Clock Works, Derby. It shows the time on four dials and plays the Westminster chimes.

Another ingenious contrivance for the prevention of the accidents to which window-cleaners are liable where the dangerous old kind of sash still obtains, is being introduced by Mr. H. Gold, of Great Eastern Street. It seems to combine the qualities of simplicity, reliability and cheapness. It is quite portable; when not in use takes up practically no room; in use it can be instantaneously fixed to a window of almost any size and shape, when it affords a secure seat, and leaves both hands of the operator at liberty.

ELECTRIC NOTES.

The Department of Science and Art has received information, through the Foreign Office, of an Exhibition of Electric Appliances to be held in Como next year, in commemoration of the centenary of Volta's discovery of the electric pile.

The Police Commissioners of Stirling had before them on Monday a minute of the lighting committee, recommending that the negotiations in connection with the scheme for the electric lighting of the town by water power should cease. After discussion the minute was unanimously adopted, and it was remitted back to the committee to carry out their previous instructions in connection with Professor Kennedy's steam-power scheme.

VARIETIES.

A Roman Catholic church, erected by the lord of the manor, Mr. C. J. Weld Blundell, of Ince Blundell, and furnished by the members of the congregation, was opened at Birkdale, Southport, on Sunday last.

The St. Rollox goods station of the North British Railway Company at Glasgow has been destroyed by fire.

A NEW bridge over the Derwent at Borrowash, which has been erected at a cost of 7,000*l.*, was opened on the 3rd inst.

THE erection of the tower which has just been added to St. Paul's Church, Peel, near Walkden, and which is a conspicuous landmark for many miles round, has cost 2,000*l.*

THE Sultan has invited the Prince and Princess of Bulgaria, with the Crown Prince Boris, to go to Constantinople, in order to attend the consecration of the new Bulgarian church of St. Stephen there on September 20.

THE dedication by the Bishop of St. Albans of the new castellated tower of St. Chad's Church, Chadwell Heath, erected, through the generosity of Colonel T. H. Sale, R.E., at a cost of 690*l.*, took place on Tuesday. By this new addition to the church the original plan has been completed.

THE malodorous and unsightly mud foreshore at Southend is likely to be shortly converted into a sand parade. It is proposed to fill in the space—which is at present useless for sea or land purposes—to above high-water mark, so as to be available at all times of the tide. There are, it is said, no engineering difficulties in the way, and the cost would be small.

CONSIDERABLE excitement prevailed in Newry on Monday morning owing to the collapse of a public-house occupied by Mr. Joseph Collins. A nephew of Mr. Collins was buried in the *débris*, and although extricated is in a very critical condition; while a man named Kearns, who hurried to the assistance of the inmates, was overwhelmed in a second fall of bricks, &c., and killed.

A NUMBER of workmen, while employed at Messrs. Greaves, Bull & Lakin's limeworks, Stockton, near Leamington, came upon a huge fossil, which upon examination proved to be a very fine specimen of an Ichthyosaurus Platydon. The greatest care is being taken to insure the excavation of this relic intact, and so far 19 feet of the fossil remains have been uncovered. The place has since the discovery been visited by a large number of Warwickshire naturalists, and the greatest interest is being shown in the proceedings.

THE well-known Pavilion Hotel, at Folkestone, has just been almost entirely rebuilt and remodelled, but its old lines have not been departed from. On entering by the Marine Terrace doorway a flight of steps from the entrance leads into the winter gardens, where concerts are held every afternoon and evening. Adjoining the lounge, which occupies the centre of the new building, is a bright and cheerful smoking-room, the windows on three sides commanding sea views. The billiard-room is light and cheerful. The public dining-room commands views of lawn and sea. The public drawing-room and ball-room adjoin. Colonel R. W. Edis is the architect. The opening of the new premises took place on Saturday afternoon.

FOR the convenience of passengers travelling to and from North Germany, Norway, Denmark and Sweden *via* Harwich and the Hook of Holland, arrangements have been made for a dining car to run between the Hook and the Rhine, thus enabling passengers to breakfast and dine *en route*. By this service passengers leaving London in the evening arrive at Hamburg the next afternoon, Berlin in the evening and Copenhagen the following morning.

THE parish church, Whitwick, Notts, was reopened for public worship, after having undergone thorough restoration, on Saturday afternoon. The church has had a new oak floor put down, a large portion of the seats have been renewed, and it has been repainted and coloured. The tower has been repaired, and a new heating apparatus provided. A handsome new double-action organ, by Taylor & Sons, of Leicester, has been erected, and this also on Saturday was dedicated. The work has occupied several months.

THE West Bromwich Corporation baths, which have been enlarged and improved, were reopened on Wednesday evening. The baths are capable of accommodating about 800 people. The first-class swimming-bath has been entirely remodelled, being 28 feet longer than the old one, and the second-class and private baths have also been considerably improved. The contract for the improvements was let to Messrs. R. & E. Woodward for 3,449*l.*, and was carried out under the superintendence of Mr. Greatorex, borough surveyor.

THE ancient chapel of Innerpeffray, near Crieff, has just undergone a thorough cleaning and repair at the expense of the heads of the three branches of the Drummond family interested in the building, viz. Earl of Ancaster, Drummond Castle, as representing the Drummonds of Perth; the Viscountess of Strathallan, Strathallan Castle, as representing the Drummonds of Strathallan; and Hon. Captain Drummond of Cromlix and Innerpeffray, as representing the Drummonds of Innerpeffray. For many years the chapel had been getting into a ruinous condition, but it has now been put into a thoroughly satisfactory state, all the ground inside being laid with gravel, and the graves of the illustrious dead being marked with green turf. The walls and roof have been cleaned, and the inside of the building now presents a very pic-

turesque appearance. The chapel, which is very ancient, is mentioned as early as 1342, and for generations it was used as the burial place of the Drummonds. It contains a handsome monument of marble, erected to the memory of Baroness Perth, and there is also a monument to the memory of Lord Perth and one of his sons. The building also contains several memorials of the Drummond families. The chapel bears the consecration marks.

THE next meeting of the Cumberland and Westmoreland Antiquarian and Archæological Society will be held on Wednesday and Thursday, 24th and 25th of this month, with the headquarters at Carlisle. During the afternoon of the first day Warwick and Wetheral churches, Wetheral Priory, St Constantine's Cells and the Written Rock, near thereto, will be visited, and also the fine culverhouse or dovecote at Corby Castle. The dinner will be at the Central Hotel, and in the course of the evening the President will present the secretary with an antique silver salver value 80 guineas, which has been subscribed for in recognition of his services to the Society during a period of thirty-one years. On the second day the members will take train to Gilsland and drive thence to Borcovicus (Homesteads), at which place the Newcastle Society of Antiquaries are excavating in systematic manner on a large scale. The works are under the direction of a distinguished scholar, Mr. R. C. Bosanquet, of Rock, near Alnwick, who has large experience in excavating for the British School of Archæology at Athens, mainly in the Greek island of Melos. The Newcastle Society have invited the Cumberland and Westmoreland Society and the Durham and Northumberland to meet with them at Borcovicus on the 25th inst.

M. DUSSAUD is now said to have perfected his system of transmitting pictures by telegraphy. He described his process at a recent meeting of the Paris Academy of Sciences, and demonstrated its thorough practicability. M. Dussaud is the inventor of the microphone, and his picture transmitter consists of a camera with a revolving screen, behind which there are a number of prepared selenium layers. These offer varying degrees of resistance to electrical action, and by their agency it is possible to reproduce light and shade as in a photograph. By standing in front of the camera a picture of any person can be reproduced at a distance. In the course of his experiments, M. Dussaud sent transmitters to New York, London, and Berlin, to be tested in this manner, and in each case an excellent photograph of people in these far-off cities was reproduced in Paris. One of the great advantages of this new system is that existing telegraph wires and cables can be used.

THE new public school which has been erected as Anderston, N.B., was formally opened on Tuesday last. The building has frontages to Stobcross Street, Elliot Street and Port Street, and with its large playgrounds has opened up and greatly improved the district. The schoolrooms are on three floors, and on the basement there are drill and play halls. There is accommodation for 1,220 scholars, fully one-third of whom would be in the infant department, which occupies the whole of the ground floor. In the centre of the infant department is a large hall for kindergarten exercises, and a special feature of the school is the abundance of light throughout. Four doorways supply ample and safe egress. The rooms are heated by means of hot-water pipes, and the Board has returned to the earlier system of distributing the heat by placing the pipes round the rooms. In view of the great increase in the cost of building of late years and the limit of cost imposed by the Education Department, the Board has in this case confined themselves perforce to a very plain but most substantial building, eschewing all decorative features.

BUILDING AND BUILDERS.

ARRANGEMENTS have been made for the erection of a new church at Elland on a site given by Lord Savile.

The Roman Catholic church of St. Teresa, Birkdale, was opened on Sunday, the 7th inst.

FOUNDATION-STONES for a Free Methodist church, Kippax, to cost about 1,500*l*., were laid on the 3rd inst.

THE Ramsgate Corporation have decided to offer prizes for competitive plans for the proposed kursaal under the Western Promenade.

THE memorial-stones of a Wesleyan church and school at Rhodes, near Middleton, have been laid. The new building is estimated to cost about 2,650*l*.

A SITE containing over 1,600 square yards has been secured for the erection of a Wesleyan mission church and schools on Messrs. Mather's estate in Liverpool Road, Eccles.

THE foundation-stone of a new edifice which is to take the place of St. James's Church, Aston, a structure formed chiefly of corrugated iron, was laid on the 6th inst. The new church will cost over 4,000*l*.

CATHEDRAL SERIES.—PETERBOROUGH: SANCTUARY AND HIGH ALTAR. SOUTH AISLE, LOOKING WEST.

PROPOSED OFFICES IN BISHOPSGATE STREET, E.C.

89 AND 91 LAMBETH WALK, S.E.

ALL SAINTS CHURCH, Cheadle Hulme, is about to be enlarged by an extension of the nave westwards, and by the addition of a new south aisle with a porch. The font will be placed at the west end of the proposed new aisle. The accommodation will be increased by 177 sittings, and the expense will amount to 1,800*l.*

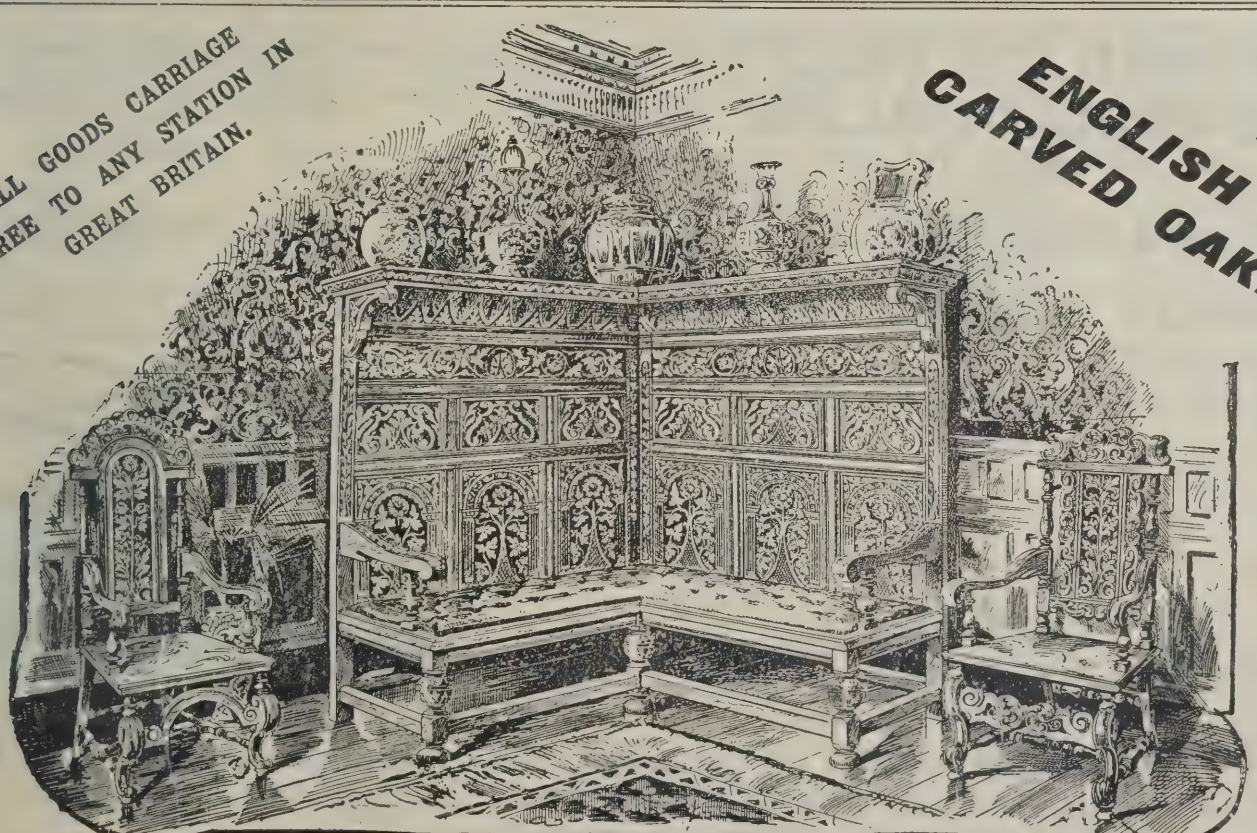
THE contract for the improvement of the Middlesbrough Docks has been let to Mr. John Scott for 382,000*l.* The works have been designed by Sir John Wolfe Barry. It is proposed to provide an entrance with 33 feet of water on the sills and 80 feet wide, and the water area of the dock will be considerably increased.

THE foundation-stone of a new parish church was laid in the parish of Gmynfe, East Carmarthenshire, last week. This parish was formed out of the large parish of Llangadock, and, the old church being in a condition past restoration, it was resolved to build a new one in close proximity to it at a cost of 1,600*l.*

A CHURCH is in course of erection at Abercynon, a rapidly developing mining town at the extreme corner of the parish of Llanwonno, in East Glamorgan, a parish which is said to contain 20,000 people. This district of Abercynon already contains 6,000 people, and the only room available for church services was a large room attached to an hotel, with seating accommodation for 250. The cost of the new church is 3,550*l.*

IN a limited competition for new girls' schools to be erected by the governors of the Wells Blue Schools, Somerset, the designs of Mr. H. Dare Bryan, architect, of Bristol, were selected. The scheme, which has been approved by the County Council Education Committee, includes a cookery school.

MESSRS. HARDIE & THOMSON, Glasgow, have prepared plans in the Italian style of architecture for the new buildings which are about to be erected for the Clydesdale Bank on the site of the old White Hart Hotel, corner of Cathcart Square, Greenock. The building is to be three storeys in height. The ground floor will be utilised as premises for the bank, the two top flats fitted up for offices, and the extreme east portion set apart for shops. The cost will be 10,000*l.*



THE Midland Hotel, New Street, Birmingham, is to be practically rebuilt at a cost of 50,000*l.* or 60,000*l.* The present arrangement of the floors and of the internal communication, which has been found to be inconvenient, and which has militated against the success of the hotel, will be superseded, and the building will be made in all respects a first-class hotel on modern lines. It is intended to put in a new stone staircase and a modern lift, and to construct a large and handsome bar in Burlington Passage. When reconstructed the Midland will have about 250 bedrooms, an increase of 150 on the present accommodation, and several new features similar to those of the Grand Hotel, Colmore Row, will be added.

PLANS have been passed for the proposed new police buildings in Crieff. The present police accommodation was found some years ago to be quite inadequate, and the police committee of Perth County Council decided to erect new buildings. They secured a site in King Street, where two very old tenements will be demolished to make room for the new structure. One of these old houses is an historic building, and bears on its front a stone block with the inscription 1736, the letters "J. W.," as well as a carved representation of a horseshoe and implements of the blacksmith's craft, part of the house having at one time been used as a smithy; and it was here that Prince Charlie, it is affirmed, had his horse shod on his way north through Crieff about the year '45. The stone is to be preserved and placed in the front of the new buildings. The buildings are to be in the Scotch Baronial style of architecture, and will be two storeys in height, with attics. The main entrance will be from King Street, and ample cell and other accommodation is to be provided.

The new Highgate Archway, which is now being constructed at a cost which is estimated at about 25,000*l.*, will have a width of 40 feet between the parapets, to be divided into a roadway of 24 feet and two footways of 8 feet each. The space beneath will be quite clear, with a span of 120 feet. It will be a steel and cast-iron bridge, with concrete, brick and Portland stone abutments, and so far as possible the old structure is being built into the new. The parapets are to be composed of cast-iron standards, with ornamental iron railings surmounted by revolving *chevaux-de-frise*.

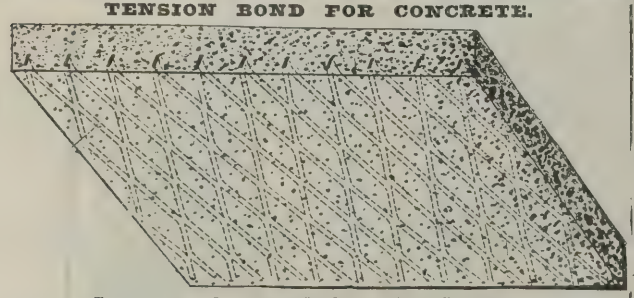
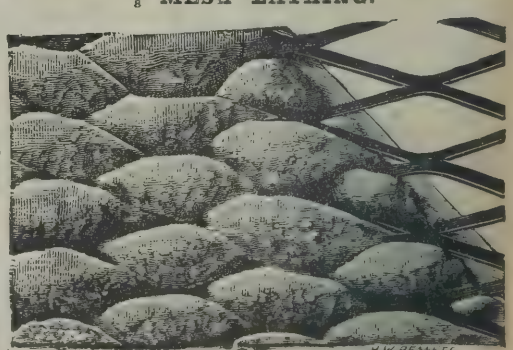
The sudden decease of Mr. Robert W. Collin, a well-known Warrington builder and contractor, took place on the 9th inst. The deceased, whose Warrington residence is in Marsden Street, has been for the last few weeks staying in the neighbourhood of Menai Bridge. At the time of his departure he complained of being unwell, but nothing serious was then anticipated. During his stay in Wales he had been far from well, but the end was sudden and unexpected. The primary cause of death, it is said, was hemorrhage on the brain. The deceased was sixty-two years of age.

As a result of negotiations the dispute in the plastering trades at Bolton is at an end. On June 18 the men struck work for an advance from 9*d.* to 10*d.* per hour, and a reduction of working hours from 52 to 49½. The question was then referred to the Lancashire and Cheshire Building Trades Federation. Conferences have been held, and the result of the last conference held on Monday is that amended rules have been signed, and the men return to work to-day. A concession is made in the hours in favour of the men, who are also granted the advance of 1*d.* per hour, making the rate 10*d.* The men, on the other hand, concede one apprentice to each four men, as against a maximum of two, whatever the number of men employed. The rules stand until the first Saturday in July next year.





SCOTTISH PLUMBING CONGRESS.

The ninth annual Scottish Plumbing Congress in connection with the movement for the improved training and national registration of plumbers takes place in Glasgow next week. At a meeting of the Glasgow and West of Scotland District Council held on the 9th inst. the arrangements, which have been in progress for some time, were matured. There will be a large attendance of master and operative plumbers and of representatives of local authorities from all parts of Scotland, as well as of others interested in improved sanitation from the standpoint of the public health. Several members of Parliament, including Mr. J. G. A. Baird, M.P., and Mr. Cameron Corbett, M.P., are also expected to be present. The president of the Congress will be ex-Bailie Crawford of Glasgow, and the proceedings will commence with a reception on Thursday the 18th by the Lord Provost in the Corporation Galleries, where the sittings of the Congress are, by kind permission of the Corporation, to take place. The proceedings will embrace addresses by several gentlemen, including ex-Bailie Crawford, Bailie Dick and others. At 1.30 the Congress will be entertained to luncheon, and in the afternoon an exhibition of sanitary appliances and of ancient and modern plumbing work will be opened by Professor M'Kendrick in the Drill Hall of the 1st V.B.H.L.I., Garnet Hill. This exhibition will contain a very fine display of manufacturers' sanitary goods, and of samples of bad and defective plumbing work, and a large collection of specimens of plumbing work sent in by apprentices and journeymen for competition for the prizes offered by the Worshipful Company of Plumbers, London, Professor Glaister, Glasgow, and others. The exhibition will remain open free to the public until Saturday the 27th. On Friday the 19th, after the transaction of business and luncheon, the Congress will visit the Dalmarnock sewage works and the Haghill refuse destructor. On Saturday they will pay a visit to Ayr, where the members will be received in the Council Chambers at 11 A.M., and afterwards drive to Maybole and other places of interest, the local arrangements being in charge of Bailie Auld and Messrs. Alexander Lyon, Samuel Cowan and J. H. Drinnan.

EXPEDITIOUS BRIDGEWORK.

It does not often happen that a few hours witness the complete removal of an old railway bridge and the substitution for it of a brand new structure, over which heavy express trains can run with perfect safety. Yet this feat of engineering has just been accomplished, says the *Daily Telegraph*, with remarkable neatness and celerity at the Finsbury Park Station of the Great Northern Railway. The precise point is that at which the Stroud Green Road is crossed by three separate iron bridges, which are a continuation of those over the Seven Sisters Road, and support one end of the station itself. In the early part of the present year the directors of the line decided to replace the middle bridge of the three, and to alter the construction in such a way as to leave the roadway beneath clear. The old bridge was supported upon heavy brick piers at the edge of each footway, but the new one is a single-span girder erection, so strongly made of steel as to be capable of bearing with ease the enormously heavy locomotives and carriages which are nowadays in use. Yet the task was by no means easy. It had to be carried out without disturbing the traffic either on the railway above or the road below, and therefore the plan sometimes adopted of building the new

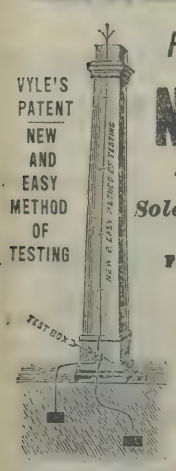
bridge all ready to be slipped, as it were, into the place of the original crossing was utilised, and with great success. Messrs. Handyside, of Derby, were entrusted by the company with the contract, and they commenced the work in March.

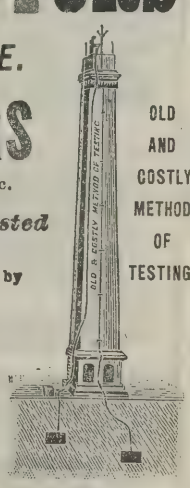
First of all a very substantial kind of scaffolding was built underneath the bridges on either side of the road. This erection was composed of baulks of timber about a foot thick each way, and calculated to bear the great weight which was to come upon it eventually. Next a miniature railway was laid along each scaffold, which, of course, ran nearly at right angles to the bridges. Then the building of the new bridge was commenced. It was constructed of heavy steel girders and plates, all bolted and riveted together, and each end of it lay upon a series of small wheeled trucks which in their turn rested upon the scaffold railway. The bridge was fully equipped with permanent way ready to be joined up to the main line directly it should be in proper position. Although it does not take long to recount the process of preparation, the affair was really a difficult one. True, the span of the bridge was not long, but the contractors were a great deal hampered by the presence of the other two bridges on either side of them, and the very narrowness of the Stroud Green Road formed an obstacle to speedy construction. However, on Sunday afternoon last everything was ready for the main operation, that of taking away the old bridge and shifting the new one bodily into its place. This task was commenced at three o'clock in the afternoon. First of all, powerful steam cranes, specially erected for the purpose, hoisted out the condemned iron girders, which weighed some 10 tons each. A very short time elapsed before all these were taken away, and for a while there was a blank space. Next ropes were attached to the new bridge, and steam winches were set to work to haul the structure slowly along on the little carriages at either end, until, in less than half an hour, the break of continuity in the railway was repaired, and when the metals on the bridge were connected to those on the main line it was again possible for trains to run over, which as a matter of fact they actually began to do about eight o'clock in the evening. Naturally a great deal remains to be done before the business is entirely finished. The brick piers in the roadway have to be demolished, and the ends of the bridge built up so as to form a continuous part of the line, but a heavy express train was seen rushing across at considerable speed, and apparently the erection was as sound and staunch as though it had been there for years.

The replacing of the Stroud Green Road bridge is only the latest of a series of such engineering feats which have been carried out during the past few years. A bridge over the Uxbridge Road, on the North London Railway, was renewed in a similar manner in about two hours. But one of the best achievements of the kind was effected a couple of years or so ago, when a bridge on the Great Eastern Railway was cleared away and a new one substituted in a very few hours. In this case the difficulty of the job was enhanced by the fact that the line at the point in question crossed a river, and that it was on the skew or slant. Yet the whole thing was done without a hitch. The principal secret of success lies in the proper construction of the small railway which supports each end of the bridge, and upon which, when the time comes, the vast mass, weighing perhaps hundreds of tons, is to be transported to its resting-place. Modern steam-cranes, winches and hauling gear also give facilities which in the early days of railroads were quite unheard of.



SLAG BRICKS.

THE American Consul at Barmen has given a version of a manufacturer's description of brick making from granulated blast furnace slag.



The direct production of building and paving stone from fluid slag is nothing new. Such slag bricks, however, did not prove a suitable material for dwelling-houses because they are, like glass, impermeable for air as well as steam. In human habitations the aqueous vapour exhaled by the occupants would condense on cold days on both windows and walls, thus rendering the rooms damp and unhealthy. On the other hand, brick manufactured from granulated blast furnace slag is permeable and hygroscopical—that is, both air and steam can penetrate them.

The first one to produce granulated slag, or slag gravel for brick-making by passing the fluid slag through water, was Eugene Langen, an employé of the Freidrichs Wilhelm mine, Siegberg, Westphalia. This process causes disintegration; silica is separated in a soluble condition, in which it easily hardens in the air and combines just as easily with caustic lime. The single grains of this slag gravel, when compressed tightly, are bound by the soluble silica; and when ground to a fine dust, so that the particles come into closer contact with

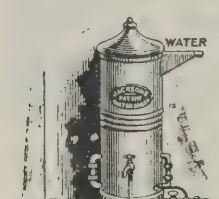
each other, the binding by the silica therein is sufficient for the production of good building bricks. Bricks from ground slag, however, require a longer time for hardening than those manufactured from granulated slag. By mixing granulated slag with dust from slag which has crumbled in the air good bricks can be produced without any addition of lime, but the hardening process is rather slow. Hardening takes place quickest in from six to eight days with bricks to which about 10 per cent. of burned and slaked lime has been added.

Granulated slag, from its passage through water, contains from 19 to 33 per cent. of water, according to its porosity, a fact which has been considered in shipping. Its weight ranges between 1,100 and 1,500 lbs. per cubic metre (35·3 cubic feet); that of ground slag runs as high as 2,900 lbs. Ground slag can be added to the mixture of granulated and lime when especially dense and strong bricks are to be produced.

The bricks may be given any shape desired, and they will preserve this shape because they are not burned. They show sharp edges and smooth surfaces, and give the best satisfaction when as little mortar as possible is used. The natural colour of slag bricks is that of greyish-white sandstone. The weight ranges, according to dryness and slag used, between 6½ and 7 lbs., or about 6,000 bricks to a 20-ton car.

The strength of slag bricks fully equals that of ordinary burned bricks; 24 to 28 lbs. per square centimetre (1·55 square inch) is usually considered the highest admissible burden for ordinary bricks. Well-hardened slag bricks can withstand, theoretically, burdens up to 160 and 180 lbs. The resistance of slag bricks to high temperature is quite remarkable. Heated to a pale red, when the carbonate of lime begins to decompose its strength will not be injured. Even if a part of the lime should be decomposed at such a high temperature, and thus rendered caustic, carbonic acid is again absorbed at a lower temperature, and the brick again becomes as strong as it was before. For the construction of chimneys and stacks slag bricks are used with advantage, as the products ascending contain a large quantity of free carbonic acid, which is delivered to the bricks. For the same reasons it is well adapted for lining lime-kilns and walling in boilers.



Slag bricks are five times as permeable as ordinary burned bricks. Pressure being equal, 10¾ square feet of lightly-burned bricks permit in one minute the passage of 23·3 litres of air; slag bricks permit the passage of from 101·2 to 113·4 litres. Their porosity also is greater than that of burned bricks; while they do not absorb water as quickly as burned bricks, they regain their permeability quicker than the latter. A burned brick filled up its pores with water in twelve hours, while a slag brick required 190 hours to get thoroughly soaked.

To test whether slag bricks have dried and hardened sufficiently to be safely used, a small piece of brick tied to a string is dipped into a cold concentrated solution of sulphate of soda and hung up at any place in a room. By the evaporation of the water in the solution and the crystallisation of the soda, which in its action resembles the formation of ice, bricks that will not resist frost are destroyed, each crystal needle carrying a little cap of the material from which the brick was produced. Not slag bricks alone, but any other can be tested in the above-mentioned manner as to their power of resistance to frost.

It is said that slag originating from puddling and Thomas pig-iron produces the best bricks, while Bessemer and foundry slag ranks second. The erection of a slag brick plant in connection with a blast furnace would cost about 5,000 dols. At several German works the cost of production of 1,000 bricks is only 10 marks (2·38 dols.). From 6,000 to 7,000 lbs. of granulated slag and 450 to 700 lbs. of burned lime are required for production of 1,000 bricks.

AMERICAN SLAG AND PORTLAND CEMENTS.

It is a somewhat surprising feature of the cement trade in the United States just at present that dealers in the puzzuolana or slag cements, instead of placing them on the market as such, like the merchants of Europe, are endeavouring to sell them as Portland cements. Portland cement is a term which has acquired a definite meaning, and a slag cement does not fall under it unless it is distorted. An attempt to sell slag cement as Portland is bound to result injuriously to the former material for two reasons. The first is that the average purchaser of a cement sold him as a Portland will be uneasy when he learns, as he certainly will, the material is really a slag cement; while the second is that the manufacturers of slag cement will find that the good qualities their article develops in service will not be attributed to their product solely, but rather to Portland cement in general; in other words, they are depriving themselves largely of the prestige won by their special grade of cement. As the distinction between the two materials is an important one, the *Engineering Record* prints an article on the subject by an experienced manufacturer of cement.

The manufacture of slag cement is beginning in this country, and while the industry in Germany and in Europe generally has almost ceased to exist, the material is coming into use on work here. In a recent award of a large contract, the question came up as to whether, under a specification calling for Portland cement, a slag cement could be delivered. The cement in question is admittedly made of a mechanical combination of slag and slaked lime; therefore it is claimed not to be a Portland cement, answering the requirements of specifications and the well-known definition of Portland cement current in scientific literature and also among cement dealers and manufacturers. In connection with the protest filed against the use of slag cement under the name of Portland cement, it is proper to call attention to the several differences between slag and Portland cements, and the definitions of the authorities on the two materials.

In a work published by direction of General William P. Craighill, late Chief of Engineers, U.S.A., Washington, Government Printing Office, in 1896, giving the results of congresses held at Munich, Dresden, Berlin, and Vienna for the purpose of adopting uniform methods for testing construction materials, which conventions were attended by representatives of the leading Governments of Europe and America, on page 38, under the head of nomenclature, are found definitions of six hydraulic binding materials. In paragraph 3, Portland cements are defined to be "products obtained from the calcination up to the verge of vitrefaction of natural marl, or of artificial mixtures of substances containing clay and lime. They are reduced to powder, and contain at least one-seventh by weight of lime for one part of the material which gives to the lime its hydraulic property. To regulate certain properties of technical importance, there may be added foreign material up to 2 per cent. of the weight without this addition necessitating any change of name." Under paragraph 4, hydraulic admixtures are defined to be "natural or artificial materials which generally do not harden under water when alone, but only when mixed with caustic limes. Such are puzzuolana, Santorin earth, trass obtained from certain volcanic tufa, furnace slag, burnt clay;" and in paragraph 5, "Puzzuolana cements are products obtained by intimately mixing powdered hydrates of lime with hydraulic mixtures, ground to the fineness of dust."

Thus, on the authority of the highest body of scientists in the world in the line of testing construction materials, and approved by the Engineering Department of the United States Government, slag cement is not a Portland cement, but is puzzuolana cement, clearly and distinctly. This general broad distinction between slag cements and Portland cements is followed in all the specifications of the various Governments of Europe. In France, under the report of the Commission des Methodes d'Essai of the materials of construction in the Department of Public Works, Paris, published in 1894, the same distinction is drawn between slag cement and Portland cement, the two ingredients being treated in separate chapters of the book, the one under the head of "Cement" on page 248 *et seq.*, and the other under the head of "Puzzuolana" on page 332 *et seq.* On page 254 of this work it is stated:—"The specific gravity of different kinds of cement present sufficient differences to be clearly noted. One could not confound, for instance, a Portland cement of which the density should oscillate about 3·10 with a slag cement of which the specific gravity cannot exceed 2·85."

On page 332, after speaking of natural puzzuolana, it states that as to "artificial puzzuolanas outside of the materials which, like the slags, enter into the composition of products sold, and tested consequently under the denominations of cement, they present no serious interest to the constructor."

The leading authority on slag cement in the world, Professor Tetmajer, in his works published in Zürich in 1893, is clear in the distinctions he draws between it and Portland cement, for after defining Portland cement, as shown above in the Convention of the Congress of Tests, of which he is president, he states that "puzzuolana cements are products which are obtained by the intimate mixture of slaked lime in powder with hydraulic materials finely pulverised," and refers especially to the slag cement as a species of puzzuolana cement under which he definitely classes it. The same definition and distinction is made in the English works written by Redgrave, London, 1895, and in Redgrave's paper before the Institution of Civil Engineers, London, in 1890 and 1891, vol. cv. So, therefore, on the broad proposition it is clearly shown that in France, England and Germany, and in the United States by publication authorised by General Craighill, there is a distinct and absolute difference, well recognised, between slag cement and Portland cement. The weight of authority, therefore, being as to this material difference, it is interesting to take the definition of the various specifications of the world and see what a Portland cement is and how far a slag cement falls within its lines. By the specifications of the United States Navy Department, Bureau of Supplies and Accounts, approved July 6, 1896, specification for Portland cement, the specific

PATENT

VULCANITE ROOFING.

Since the introduction of the patent Vulcanite Roofing into this country it has been adopted by a great number of leading architects for Public and Private Buildings, Hotels, Schools, Hospitals, Theatres, Mills, Warehouses, Breweries, Shops, Villas, Dwelling-houses, &c.

The temperature of the rooms immediately beneath the roof is more even in winter and summer than under any other roof. When properly laid repairs are never required, and all roofs are guaranteed. The roof-surface can be used as a garden, or for any other purpose. The cost of construction is less than even for a slate or tiled roof.

SHEET ASPHALTE for DAMP-COURSE, WATERPROOFING VAULTS, BRIDGES, TUNNELS, &c., is manufactured ready for use in lengths of 40 feet, and any width up to 40 inches, being more convenient than the usual damp-course slabs, and saving laps. Price lower and quality much superior to any similar article in the market.

SHEET ASPHALTE for ROOFING SHEDS, LIGHT BUILDINGS, &c., and for SARKING under slates or tiles, manufactured in five different qualities and in rolls of 15 superficial yards. It is easily laid, very inexpensive, much superior to felt roofing, and requires no annual coating.

Full particulars, Catalogues, Detail Sketches, Estimates, re Vulcanite Roofing; Samples, Prices, &c. re Sheet Asphalte, free.

THE PATENT VULCANITE ROOFING & ASPHALTE CO., LTD.,

28 VICTORIA STREET, WESTMINSTER, LONDON, S.W.

Inquiries from the North of England, Scotland, and Ireland, please address to Laganvale, Belfast.

Agents wanted in all districts where not yet represented for laying of Vulcanite Roofs and Sale of Sheet Asphalte.

Vol. LIX. of THE ARCHITECT. Handsomely Bound in Cloth, Gilt Lettered, Price 12s. 6d. Office—175 Strand, London, W.C.

gravity shall not be less than 3, and the material must have its final set at the end of eight hours. By all the authorities above referred to, as well as "Schoch on Mortar Materials," Berlin 1897—Candlot, Heath, Redgrave, Spalding, Tetmajer and other writers—slag cement has a specific gravity of from 2·7 to 2·8, and attains its final set in from 12 to 24 hours. Thus, under the specification of the United States, slag cement is not a Portland cement.

In the French specifications of the Ponts et Chaussées, Portland cement is defined to be "the product of the grinding of clinkered rock obtained by the burning to a point of softening of an intimate mixture of carbonate of lime and argillaceous matter, rigorously combined and chemically and physically homogeneous in all its parts."

By the standard tests accepted by the German Government in a decree of the Minister of Public Works dated July 28, 1887, Portland cement is a material resulting from the calcination, carried to the point of incipient fusion, of an intimate mixture of lime and argillaceous substances as its essential components; such calcination being followed by the grinding of the product to the fineness of flour.

In Switzerland, Portland cements are described to be the product obtained by the burning to the point of vitrification of hydraulic lime, stones, or of mixtures of argillaceous and calcareous materials, which are subsequently ground and reduced to fine powder. Portland cement in addition must contain a minimum of 1·7 parts lime to the unity of hydraulic materials.

In Austria, in the specifications of the Austrian Engineers and Architects' Association 1890, Portland cement is defined to be "compounds of natural marls or artificial mixtures of clay and lime-bearing materials which are burned to vitrification and are ground to great fineness, and in which the calcareous material shall at least be 1·7 to the unity of the argillaceous."

In Russia the Minister of Roads and Railways defines Portland cement to be "a product made out of natural marls or artificial mixtures of materials in which clay and carbonate of lime are contained, and which materials are subsequently turned to clinker, and are therefore ground to the fineness of flour."

In the English specification, quoted with approval on page 290 of Dr. Schoch's book, Portland cement is described to be "an intimate mixture of carbonate of lime and clay, which shall have been burned together without any foreign material, and it shall have been ground to great fineness."

In all these definitions of Portland cement it will be noticed that running through the whole line are certain definite requirements, and the best way to show the difference between Portland cement and slag cement is to place in parallel columns the principal elements of difference.

Under the facts above given and the material differences shown, it seems hardly necessary to add any further facts to prove that slag cement is not Portland cement, even though the label on the top of the barrel may say it is. The industry is a new one in this country, but is an old one in Germany, and from consular reports to the State Department, 1895, page 224, *et seq.*, it will be seen from the reports of the consuls at Frankfurt, Magdeburg and Düsseldorf, that the slag industry, which was successful there in 1890 and thereabouts, has steadily dwindled away, until to-day there is but a single works in existence in Germany, and Candlot, referring to this industry, states that no new works have been built in Switzerland, while in Belgium but one remains, and in France there are but three. It would, therefore, seem to remain for the slag cement manufacturers to explain why it is that if slag cement is as good as Portland, it is sold in this country, not as slag cement but as Portland cement, while all imported slag cement coming here is labelled puzzuolana cement.

DANVILLE ASBESTIC PLASTER.

THAT truly extraordinary mineral which bears the name asbestos has long been known as possessing the property of indestructibility by fire or any other human agency. For this reason it received its name, which, as scholars are aware, signifies "undestroyed," or indestructible. By that race of natural poets—the Greeks—it was also called "amianto," or unpolluted, for the reason that it is not possible to defile it in any way.

In the popular mind, as well as to some extent in the minds of architects and builders, its indestructibility or power of resisting fire is the chief, if not indeed the only, special characteristic of asbestos. This belief has been created, or at any rate largely fostered, by the fact that the fireproof qualities of asbestos have from time to time been displayed at public entertainments.

It cannot, however, be too widely known—especially among professional men—that although asbestos is absolutely fireproof, yet that important feature by no means exhausts its special

merits. Before dealing with these other virtues it will, however, be convenient to say something of asbestic as the particular kind of the famous mineral with which we at present have to do.

Asbestos is found in several parts of the world, a good deal being brought from Italy, though there are asbestos mines in Spain. At the Danville mines in Quebec, Canada, however, there is found a kind of asbestos which differs in one very important respect from all other varieties. In the ordinary form in which asbestos is found the mineral or rocky mass in which the fibre is embedded is valueless, but in the Danville asbestos the mineral mass is in several ways quite as valuable as the famous fibre itself. To this surrounding mass the term "asbestic" has been given, and it is to its merits as a material for plaster that we now propose to direct attention.

That asbestic is a perfect non-conductor of heat of course goes without saying, and thus asbestic plaster will keep a room cool in hot weather and *vice versâ*. Then asbestic is a non-conductor of sound, and thus the plaster should be eminently suitable for churches, lecture-halls, and concert-rooms, and other places into which the entry of external and the escape of internal sound are alike undesirable.

Asbestic plaster is fibrous and very elastic. Once set, it will never crack or crumble, and nails enter as freely as into wet plaster, and without injury other than the hole, which can be readily made good. Nothing besides the asbestic itself being used in this plaster, it is not only vermin proof, but cannot generate organisms of any kind. Thus its value from a sanitary point of view is of the highest. Moreover, the plaster adheres with great tenacity, and is therefore peculiarly suitable for ceilings, especially by reason of its filtrative powers, which, in the event of an overflow from the room above would prevent any stain, while the ceiling would suffer no injury.

In manipulation, asbestic plaster effects a great saving of labour, as its application is much easier than that of any other plaster. It is also quite as suitable for metallic as for wood lathing, especially as it is a preventive of corrosion as well as of the action of heat.

Of the power of resisting the action of heat which is possessed by asbestic plaster, mention has already been made. Its power of resisting the much more destructive action of heat and water is equally noteworthy. As General Smith, the United States Government supervising architect for public construction, says in a recent and able report, "fireproofing to be worthy of the name must resist the combined action of heat and water and be a non-conductor of heat." Such a material, the General goes on to say, he found in asbestic plaster and in that alone. The same high authority goes on to point out the great value of asbestic plaster as a covering for steel beams and girders. These rapidly buckle under the action of heat, and when subjected to the action of cold water at once collapse and become worse than useless. As asbestic plaster may be heated to red heat without marring its durability, steel or iron protected therewith would afford a resistance to fire attainable by no other known means. Thus we have no hesitation in commending Danville asbestic plaster to the notice of our readers, and in advising them to secure fuller details than those for which we have been able to spare space, which they may easily do by communicating with the Asbestos and Asbestic Company, Limited, at 27 Billiter Buildings, London, E.C.

MARYLEBONE COAL DEPOT.

The London Extension of the Great Central Railway has been in course of construction for nearly four years. The main line is now practically finished, and is being inspected in sections by the Board of Trade. It is now open for coal traffic.

The Marylebone coal depôt covers an area of about six acres, and has been laid out upon what is considered by coal merchants to be the most suitable plan for the economical carrying on of their business. The coal trains will be brought to Neasden, where the company has enormous storage sidings, and there they will be worked down to the depôt as they are required by what is technically known as "special pilot working." Along the south side of the yard are an inwards line of rails for the full waggons and an outwards line for the empty ones. Running at right angles are nine pairs of lines, nearly the width of the yard, with a broad road between each pair. On this road the delivery or street vehicles will come and take the coal straight out of the railway waggons. This arrangement enables a merchant to have one or more of these stands to himself, and also tends to secure the coal against breakage. The waggons are worked into and out of the cross lines from the delivery and receiving lines by means of turntables. These cross lines provide standing accommodation for upwards of 300 waggons, but the applications from merchants have so largely exceeded the space available that the company have already applied for Parliamentary powers to double the size of the depôt. The company is in direct communication with the Yorkshire, Derbyshire, Nottinghamshire and North Wales coalfields, whence an immense volume of coal is ready to be taken over the new line to London. Ample office accommodation for merchants and factors is provided in the yard, as well as extensive ranges of stables.

But the coal depôt is only a small portion of the London terminus, which covers some 60 or 70 acres. It is approached from the north by a double line, through a tunnel about a mile long. Then follows the "cut and cover" work, completed for six sets of rails, four of which end in "dead ends" at the southern portal of the tunnel, and will be used until a second tunnel becomes necessary for storage sidings. All the lines pass over the Regent's Canal, and there the first lot of goods lines leave the main line to the right, or west, and follow round the edge of the canal. The canal, which has been widened, here forms a long basin, about 100 feet wide, and is retained by a fine wall, along which the barges will lie. On this wharf there will be a shed covering four lines of rails, and six hydraulic cranes are in position, so that goods will be lifted out of the waggons into the barges, or *vice versâ*, and sent direct to the ship's side at the docks. A little further south the coal line into the coal depôt leaves the main line and makes a dip in order to get under Grove Road. Still a little further south the lines into the general goods yard branch off to the west. The main feature of the goods yard is the magnificent warehouse which will shortly be finished. It has five floors, each 255 feet by 350 feet, giving an aggregate storage area of 12½ acres. It is being fitted with all modern appliances for expeditiously handling goods. The building is fireproof, and the skeleton is composed entirely of steel girders and columns. After passing the goods yard the line splits up into the five lines of the terminal passenger station, which will have two arrival and two departure lines and one siding line against the east wall. The platforms are 1,000 feet long. At first the company will have no local traffic, but recent proceedings in the Parliamentary committee-rooms indicate that this will not be the case for long.

There is a broad road or promenade between the station building and the fine hotel designed by Colonel Edis. It is expected that the hotel will be opened next spring. It should also be mentioned that Colonel Edis designed the front elevation of the station building, though all the engineering work of the southern and London divisions has been designed by Sir Douglas and Mr. Francis Fox, whose resident engineer for the London division is Mr. Edmund Wragge. The contractors are Messrs. Firbank. In addition to the works and buildings so briefly indicated, there are gasworks, extensive electric-lighting works, a large hydraulic pumping station, carriage works, and stables for 700 horses, all of which are in a forward state.

THE INGLIS MEMORIAL HALL, EDZELL.

For the new hall at Edzell a clock and bells have been made and erected by Messrs. Gillett & Johnston, clockmakers and bellfounders, of Croydon. The clock is what is known as a Westminster quarter one, *i.e.* being constructed to chime the Westminster quarter hours, in addition to showing the time and striking the hours. The frame which contains the wheels is of cast-iron, cast in one piece for perfect rigidity, and the "main" or largest wheels measure 10 inches, 12 inches and 12 inches in diameter for the going, striking and quarter parts respectively. The clock is fitted with the "double three-legged gravity escapement," and a compensated pendulum constructed to withstand all variations of temperature. It beats once in every 1¼ seconds, and the cast-iron "bob" at foot weighs 90 lbs. The dials or faces are four in number and measure 4 feet 6 inches in diameter. They are of cast-iron, glazed with opal glass for illumination, and are fitted into cast-iron spandrels, built into the masonry, and, being tastefully decorated and gilt, present a very pleasing appearance. There is an apparatus attached to the clock for the purpose of turning the gas up and down automatically, according to the seasons of the year, and the works are also provided with a small dial to enable any one to take observations of the time from inside the tower, and for convenience in setting the outside hands when necessary. The bells are five in number, and are of the following weights and dimensions :—

No.	Size. Diameter at Mouth. Inches.	Weight. Cwts.	Qrs.	Lbs.	Note.
1.	26½	4	0	21	F sharp
2.	28	4	3	12	E
3.	30	5	2	7	D
4.	36	7	3	10	A
5.	39	10	0	19	G

The following inscription is cast upon the largest bell :—"This bell was cast on July 30, 1897, for the Inglis Memorial Hall, Edzell, erected and endowed by Lieutenant-Colonel Robert William Inglis, V.D, for the benefit of his native parish, and in loving memory of his father and mother." It may interest many to know that the weights necessary to drive the clock scale in the aggregate over 16 cwts.

WEST BANGOUR NEW LUNATIC ASYLUM.

A new lunatic asylum is to be erected at West Bangour from the designs of Mr. Hyppolyte J. Blanc, who, with a view to making his building as perfect as possible, made a tour of inspection of various asylums at home and on the Continent, the various good points of which he has as far as possible combined. The characteristic aimed at by the architect in the outward treatment of the designs is variety of expression, consistent with the internal requirements. In some instances a little more architectural style has been infused into the design, to relieve the eye as far as possible from any sense of uniformity or monotony. Having regard to the conditions of site, the position chosen on the plan for the main entrance is suggested as that affording the largest area of a uniform surface, and it is therefore most convenient for receiving and delivering all heavy goods for the colony.

The administrative block is placed in the middle of the medical and hospital blocks, conveniently near the localities to be served. The porter's house is placed at the back, with separate access and staircase, but with through communication to the main building. The plans of the kitchen block provide for the requirements, and show all the fittings and apparatus requisite for cooking for 1,000 patients and 200 officials. These are of the very latest construction, and have been found to work admirably in other modern asylums where they were seen. Bedroom accommodation for cook and assistants is also provided within the block. The stores block and the kitchen block are attached, and have through private communication. An abundance of lighting is afforded by means of continuous cupolas of clerestory side-sashes, with opening frames for ventilation, under simple and easy control. By this mode of construction the heating effect produced by ordinary roof-lying lights is destroyed. The church is designed to meet the requirements of Presbyterian or ritual service as may be desired.

The recreation hall is placed almost in the centre of the whole site. The floor area is unobstructed by pillars, and ample provision is made for stage and dressing-room requirements. At the main entrance are two cloak-rooms ; and for an increase of accommodation a gallery can readily be constructed over the recess between the two vestibules, to hold 130 persons. There are four doors of access, any two of which can be for males, and two for females, if desired. In treating the exterior of the hall, one of the vestibules has been designed to carry a lofty tower. In that tower it is proposed to place tanks of 30,000 gallons capacity, wherein water may be stored for the general service of the several blocks or for the washhouse, and also as a supply for fire-hydrants. Above these is a clock chamber, placed at such elevation as will conveniently be viewed from any part of the colony. The hall is prominent, and consistently with the idea of giving special consideration to prominent parts, it is more decoratively treated than are some other buildings. The bath-house is lighted from clerestory windows placed high. In other asylums it is recommended to have screens between each bath, and so the plan provides for screens of moderate height and projection. Each bath spills into a continuous gutter in the floor, and so all complication of plumber-work is overcome. The baths are proposed to be of fireclay, glazed white inside and outside, placed upon moulded blocks raised from the floor. The mortuary block is planned upon the lines of the best-equipped mortuary in this country. A special addition shown upon the plans is a duplicate mortuary for the sexes, a dissecting-room and a refrigerator. The situation of the mortuary has been specially considered. It is comparatively near the hospital, and from it bodies may be removed outside the precincts of the colony without observation by any inmates. The laundry block is quite close to the kitchen and store block. The fittings proposed are selected from the best of those found in use in good modern asylums. As in other blocks named, the natural lighting here is by continuous upright glazed cupolas, and the means for ventilation are of the simplest and most efficient construction, namely, opening frames by means of cords and pulleys. The boiler and engine-house block immediately adjoin the store block. The accommodation provided is considered ample for the colony. The steam heating for kitchen, &c., may be served by one or two boilers. One is required for the electric lighting, and one—a spare one—for emergencies. The boilers are of necessity placed at a lower level than the ground, and the coal store adjoining, capable of housing 400 tons, is also placed at the same level, because the coal would thereby be more easily delivered to the cellars. The dynamo-room is purposely delineated of ample space to admit of an increase in the number of dynamos, and also to afford space for storage batteries, which may be found useful. The equipment can quite readily be limited to the requirements of 720 persons in the meantime. The bakery is designed to meet the requirements of 1,200 people. It is planned upon the best modern models. The flour is delivered upon a gallery floor by an electric hoist, and descends through a shoot into the special dough-mixing machine placed to receive it. The ovens are a special patent. They are not fired in the usual manner from the front, but are heated from an area behind by coke, and may be used continuously for hours, being always maintained at a uniform high temperature. The workshop block is, for obvious reasons, attached to the engine-room block. It is virtually more than a block, forming in its complete condition three sides of a courtyard. The nurses' house, for obvious reasons, is placed at the extreme west end of the site, being at a convenient distance from the medical section. The strain of their special duties demands perfect quietness in their retreat. In the plan the effort has been to group the accommodation prescribed in the most economical and convenient manner, and yet to give a certain degree of individuality to the whole block. Special accommodation for a matron is also provided. The medical superintendent's house is placed where it can be readily accessible to visitors and inquirers, namely, within ready view and easy reach of the main entrance. The attendants' cottages are planned for varying accommodation of three and four apartments. Those of three apartments have no separate bathroom, while those of four apartments have. The series is designed with a view to picturesqueness, without unnecessary ornamentation, but with sufficient form to give them architectural interest. The infirmary and sick-room blocks complete the group fronting the high land on which the medical section is placed. The situation is selected for its comparative airiness, as well as the other advantages of convenience. The hospital block is arranged that one side or half is a counterpart of the other. The kitchen is arranged in the middle. A doctor's room is also provided. A feature of the plan is that at the end of the wards are two single rooms, one of which is for a moribund patient, who, after death, can be removed by the outside door without having to be conveyed through the ward. The arrangement has received careful consideration to secure separation of sexes and easy communication throughout upon an economical form of construction.

The asylum houses are arranged to supply the accommodation required, and variety is sought to be gained by varying the areas and consequent accommodation of dormitories in the several blocks. For the industrial or non-medical section ten separate schemes for villas are submitted—five for men and five for women. The aggregate number of 150 of each sex has been divided as follows :—One villa of 25, one of 26, one of 28, one of 32 and one of 40 patients.

Fire hydrants and hose chambers are provided for in every block at convenient places in the corridors or in the staircases. No special fireproof construction is contemplated. There is comparative immunity from fire risks by the isolation of the different blocks. The lighting is proposed to be by electricity, with various candle-power lamps to suit the respective situations, the supply main cables being underground and the house cables carried in steel tubes, all on the most approved system. The ventilation of the various dormitories and day-rooms is provided for by means of fresh-air inlets in the window recesses at the floor levels, under key control of the attendants. Radiators are proposed to be placed in the window recesses, so that in winter the incoming air would be warmed, while in summer the air would be admitted by the same openings in a natural state. For the release of vitiated air grated openings are proposed to be placed in the walls near the ceilings, and led in specially constructed glazed brick flues into an outlet shaft and ventilator in the roof. A fan in the ventilating shaft driven at any time when required by an electric motor is much more satisfactory. All windows are intended to open, but by means of a small brass bracket permanently screwed to the case the extent of the opening is limited to about 7 inches, which is quite serviceable for all requirements. The cost of the building to accommodate 1,000 patients is set down at 235,000*l.*

LONDON BOARD SCHOOLS.

In the annual report of the works committee of the London School Board is an abstract of the work done during the year ended March 25. From it the increased accommodation which has been sanctioned by the Board and the Education Department can be judged. The report, after stating what action has been taken with regard to the purchase of twelve sites for new schools and additional land for nineteen existing schools, with regard to which compulsory powers were obtained in 1896-97, sets forth a list of sites for twelve new schools and for enlarging schools or playgrounds or for general improvements. During the past year the Board agreed to purchase various interests in sites at a cost of 84,361*l.*, the surveyors' fees amounting to 583*l.*, and, including these amounts, the total cost of the sites purchased up to the end of the year under review was 3,300,165*l.*, the surveyors' fees, &c., being 446,931*l.* According to a table prepared by the finance department, the cost of the sites for 350 schools, the accounts of which had been completed on September 29 last, was 6*l.* 14*s.* 6*d.* per child, and the average cost per head for school buildings was 13*l.* 14*s.* 1*d.*, and for furniture and fittings 10*s.* 7*d.* Up to Lady Day, 1897, the total number of permanent schools which

had been erected and opened was 418, and during the year under review twelve new schools and eight enlargements were opened. The twelve new schools were opened—one in Chelsea, one in Finsbury, one in Greenwich, three in Hackney, one in East Lambeth, four in West Lambeth and one in Tower Hamlets. The total accommodation thus provided was for 12,948 children, and the cost of the sites, buildings and furniture was 352,484*l.* 16*s.* 7*d.*, or an average cost per head of 27*l.* 4*s.* 5*d.* The enlargements were carried out in Finsbury, Greenwich, West Lambeth, Southwark and Tower Hamlets, and provided additional accommodation for 2,910 children at a cost (exclusive of site) of 83,146*l.*, or an average cost per head of 28*l.* 11*s.* 5*d.* Loans were authorised by the Education Department in respect of the twelve new schools amounting to 364,668*l.*, and on account of the eight enlargements and sites amounting to 138,278*l.*

Additional school provision has been made to the following extent:—Tenders have been accepted during the year for erecting nine new schools to provide accommodation for 7,719, and for carrying out thirteen enlargements of schools to provide accommodation for 3,863 children. The new schools will be erected—two in Greenwich, one in Hackney, two in East Lambeth, two in West Lambeth and two in the Tower Hamlets—at a total cost of 173,305*l.*, or 22*l.* 9*s.* per head. The enlargements will be made—two in Finsbury, four in Greenwich, one in Hackney, one in West Lambeth, three in Southwark and two in the Tower Hamlets—at a total cost of 91,702*l.*, or 23*l.* 14*s.* 9*d.* per head. The tenders include the provision of halls which are not counted in the accommodation of the schools, the provision of centres, and in all cases a drawing classroom. In four cases a playground is being provided on the roof. Three of the schools are being erected under the special arrangements made with the view of reducing the cost. With regard to the enlargements, the variations in cost arise mainly from the fact that the opportunity is taken to improve the existing schools by providing halls, &c., so as to make them thoroughly efficient. Tenders have also been accepted for erecting or providing, among various other works, fourteen cookery centres, seventeen laundry centres, sixteen manual training centres, seven schools for special instruction, rooms for the teaching of the upper standards at nine schools, a blind centre, two housewifery centres, draining and other works at nineteen schools, an infirmary and isolation ward in connection with the *Shaftesbury* training ship, at a cost of 3,400*l.* Sanitary works have also to be carried out at twenty-one schools, and the total amount of the tenders accepted in respect of seventeen of these schools is 23,115*l.* The system of carrying out repairs to school buildings by workmen employed direct by the Board is being continued in nine of the eighteen districts of the clerks of works for repairs.

The following work was in hand at Lady Day last. Fifteen schools were in course of erection, providing accommodation for 13,789 children, and fourteen enlargements giving accommodation for 4,467; thirty-two additional sites for new schools had been or were being purchased, the schools to be erected on twenty-five of which would provide for 23,157 children; twelve sites for new schools had been scheduled, the schools to be erected on four of which would provide for 3,494 children; eighteen enlargements of schools had been sanctioned by the Education Department, providing for 5,840 children, and the Education Department had sanctioned the provision of sites in seven districts, which would be scheduled next session, the schools to be erected on four of which would provide for 2,820 children. The report adds that the playgrounds of 236 schools were opened on Saturdays for the use of children and forty-seven were also opened on Sundays.

DURHAM NEW SHIRE HALL.

THE new Shire Hall, Durham, which was opened on the 26th ult., has been erected from the designs of Messrs. Barnes & Coates, architects, of Sunderland and West Hartlepool. The foundation-stone of the building was laid by the Earl of Durham on April 25, 1896, so that rather more than two years have been occupied in its erection. The entrance is in the centre, with a fine balustrade extending on either side the full length of the building. The approach is up a fine flight of red Mansfield stone steps, about 30 feet wide, through an enriched archway. The gates are of wrought and hammered iron. The building is of red terra-cotta, with dressings of the same material, from Messrs. Monk & Newell, of Ruabon, and the roofing is of green slates. The site being in a hollow, a fine tower with clustered shaft supporting a copper dome has been designed, which adds to the dignity and prominence of the building. The entrance to the Weights and Measures Office is from the street level at the north-west corner. In the basement are the county clerk's strong-room and the county surveyor's plans and sample-rooms, the caretaker and the

CASES for BINDING THE ARCHITECT. Price 2s.—Office: 175 Strand, London, W.C.

heating chamber, &c. The council chamber, committee and retiring-rooms and the county clerk's department are on the ground floor. The first floor contains the county surveyor's, medical officer's, accountant's and technical education secretary's department, while on the second floor are provided the photographing-rooms of the county surveyor, the laboratory of the medical officer and the education secretary's library. The county clerk's strong rooms are well lighted and ventilated, and easily accessible. The caretaker's rooms, although away from the business portion, are conveniently placed, the entrance being from the east side, and quite distinct. The council chamber block is placed on the opposite side of the hall to the county clerk's office, and is self-contained, while the entrance to the upper floor is quite independent of either, both of which are absolutely private. The council chamber, which is two storeys in height, is on the axial line of the building, and though effectively isolated, is of easy access from all parts. The committee, chairman's, and retiring-rooms are arranged on either side of the council chamber lobby, and are provided with an excellent lavatory block. The council chamber is in the form of a horseshoe on plan, and is admirably adapted for the purposes of debate, all unnecessary corners, &c., being dispensed with. The chairman's seat is placed on a daïs, with the vice-chairman's and county clerk's on either side. The daïs is constructed to prevent draughts and to also act as a sounding board. The officials are placed together in front of the chairman, and press boxes are arranged on either side in good positions. The council chamber is 45 feet in diameter, 30 feet in height, the top portion being circular. It will accommodate 100 members, in addition to the officials and reporters. The walls are enriched with marble columns and panels and carving, and the windows filled with stained-glass, representing the arms of the county and principal boroughs. The roof is coved and domed with pendentives and arches ornamented in relief. There is a public gallery situated above the council chamber entrance. This is reached by way of the first-floor corridor. Between the council chamber and the county clerk's department is the chairman's room. The waiting-rooms are next placed for the convenience of deputations. The whole of the corridors are well lighted from the area windows. Great attention has been paid to the position of the ante-room and main staircase. The former is a large hexagonal room 24 feet high, finely panelled with oak, and the windows glazed with coloured glass. There are three handsome committee-rooms and a retiring-room, the largest being 42 feet by 21 feet. The main staircase is on the front immediately adjacent to the hall. It is beautifully panelled throughout with faïence from the Burmantofts Faïence and Tile Company, Leeds, as are also the hall and the ground-floor corridors. The steps are of marble, and the balustrade is red terra-cotta. The drawing office in the surveyor's department is one well lighted from two sides. The walls of every strong room are carried up from the ground level. The floors over corridors are fireproof, and are laid with wood-block flooring. The lavatories and w.c. blocks are well arranged and ventilated, and disconnected from the corridors by a lobby. The buildings are heated throughout by low-pressure, and the council chamber is heated on the Plenum system. A large ventilating sunburner is placed in the council chamber. All the principal offices have open fires.

PATENTS.

[*This List of Patents is compiled specially for this Journal by Mr. G. H. Rayner, of the firm of Rayner & Co., Consulting Patent Agents, 37 Chancery Lane, London, W.C., from whom all particulars and information relating to Patents may be had gratuitously.*]

Applications for Patents.

16341. W. Tharme, for "Improvements in preparing or treating clay or the like for making bricks, tiles and other articles."

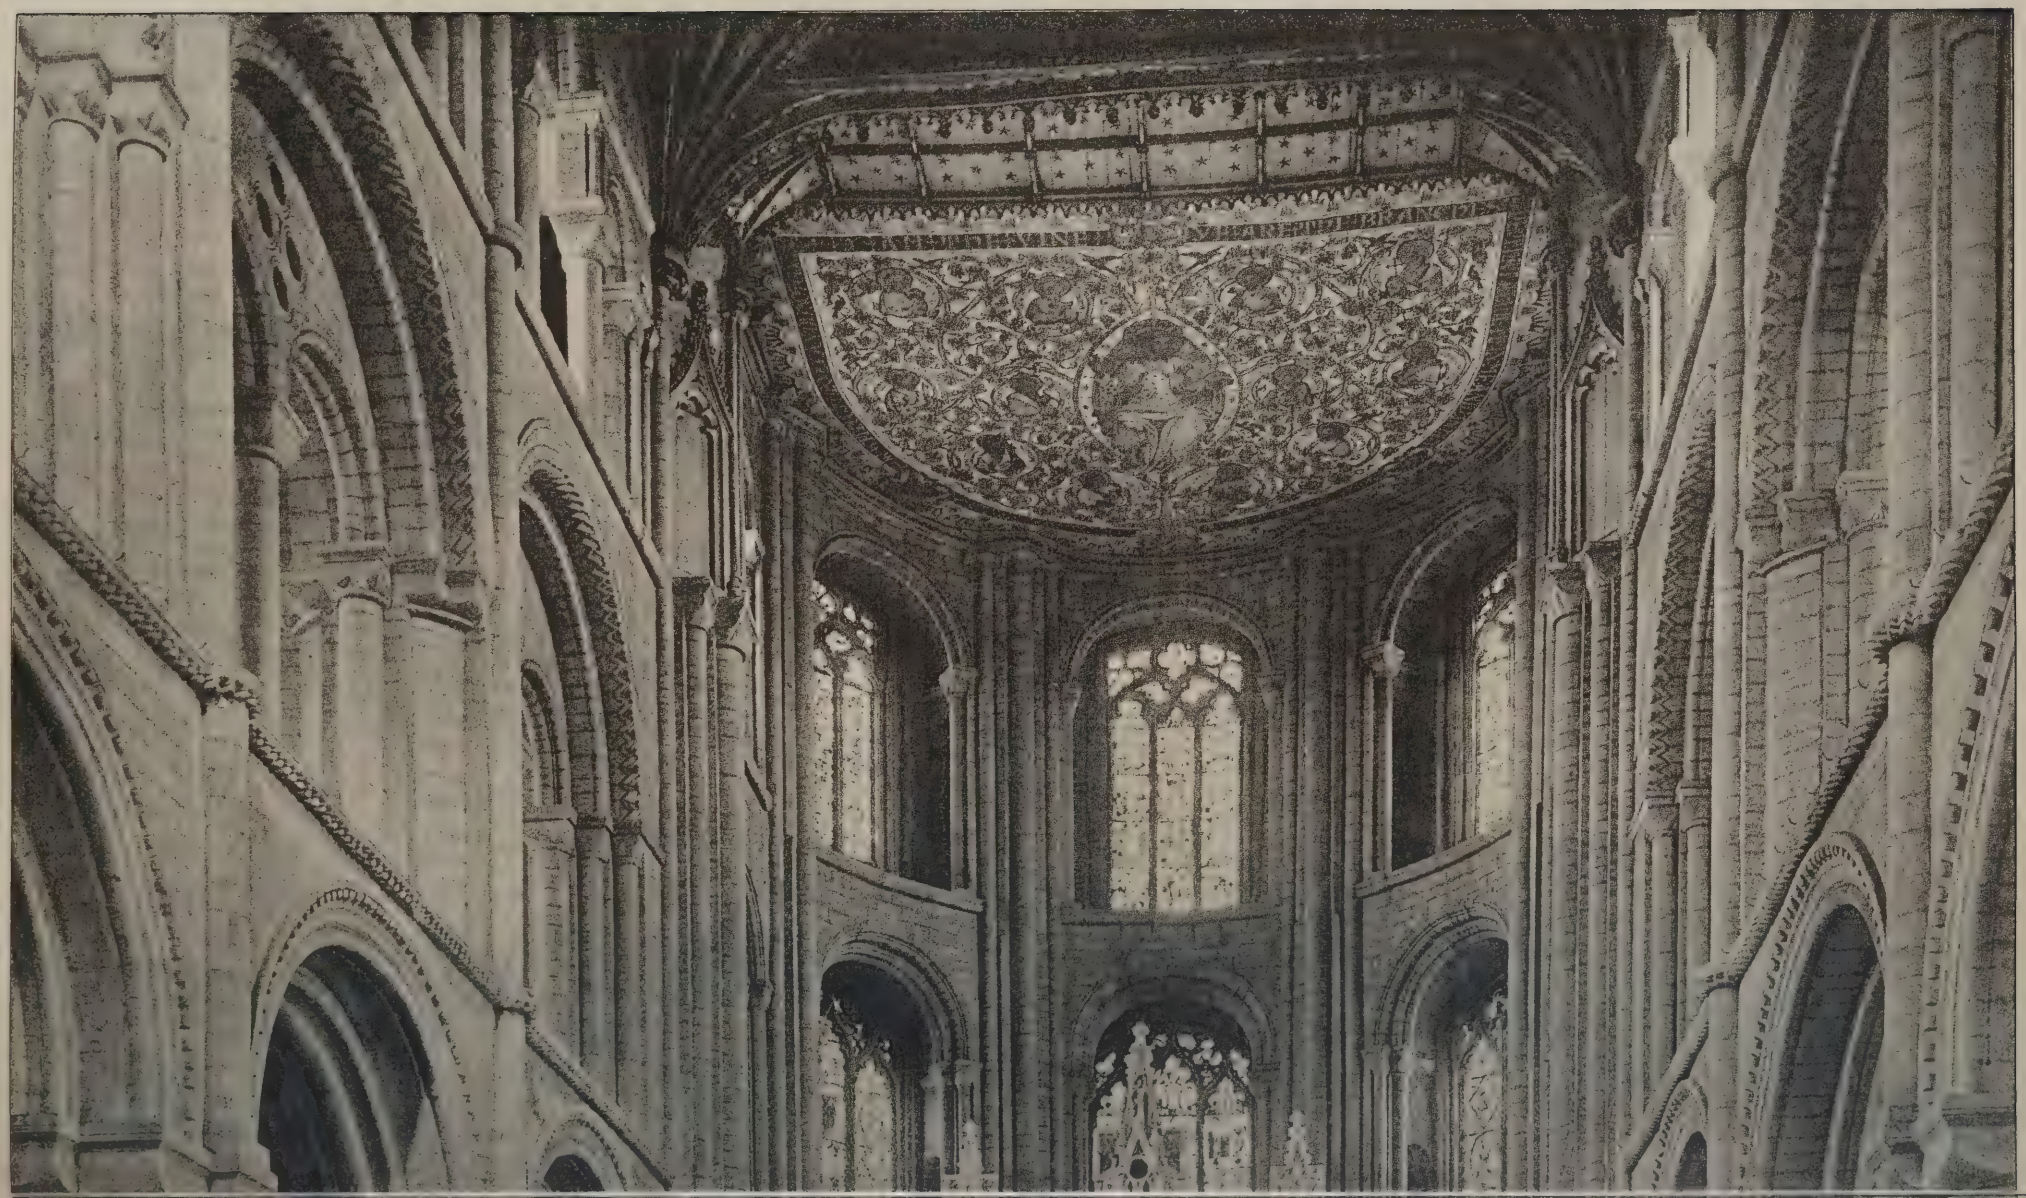
16416. H. Alexander, for "Improvements in brick-making and pressing machines."

16417. H. Burridge, for "Improvements in kilns or ovens for firing bricks and other ceramic goods."

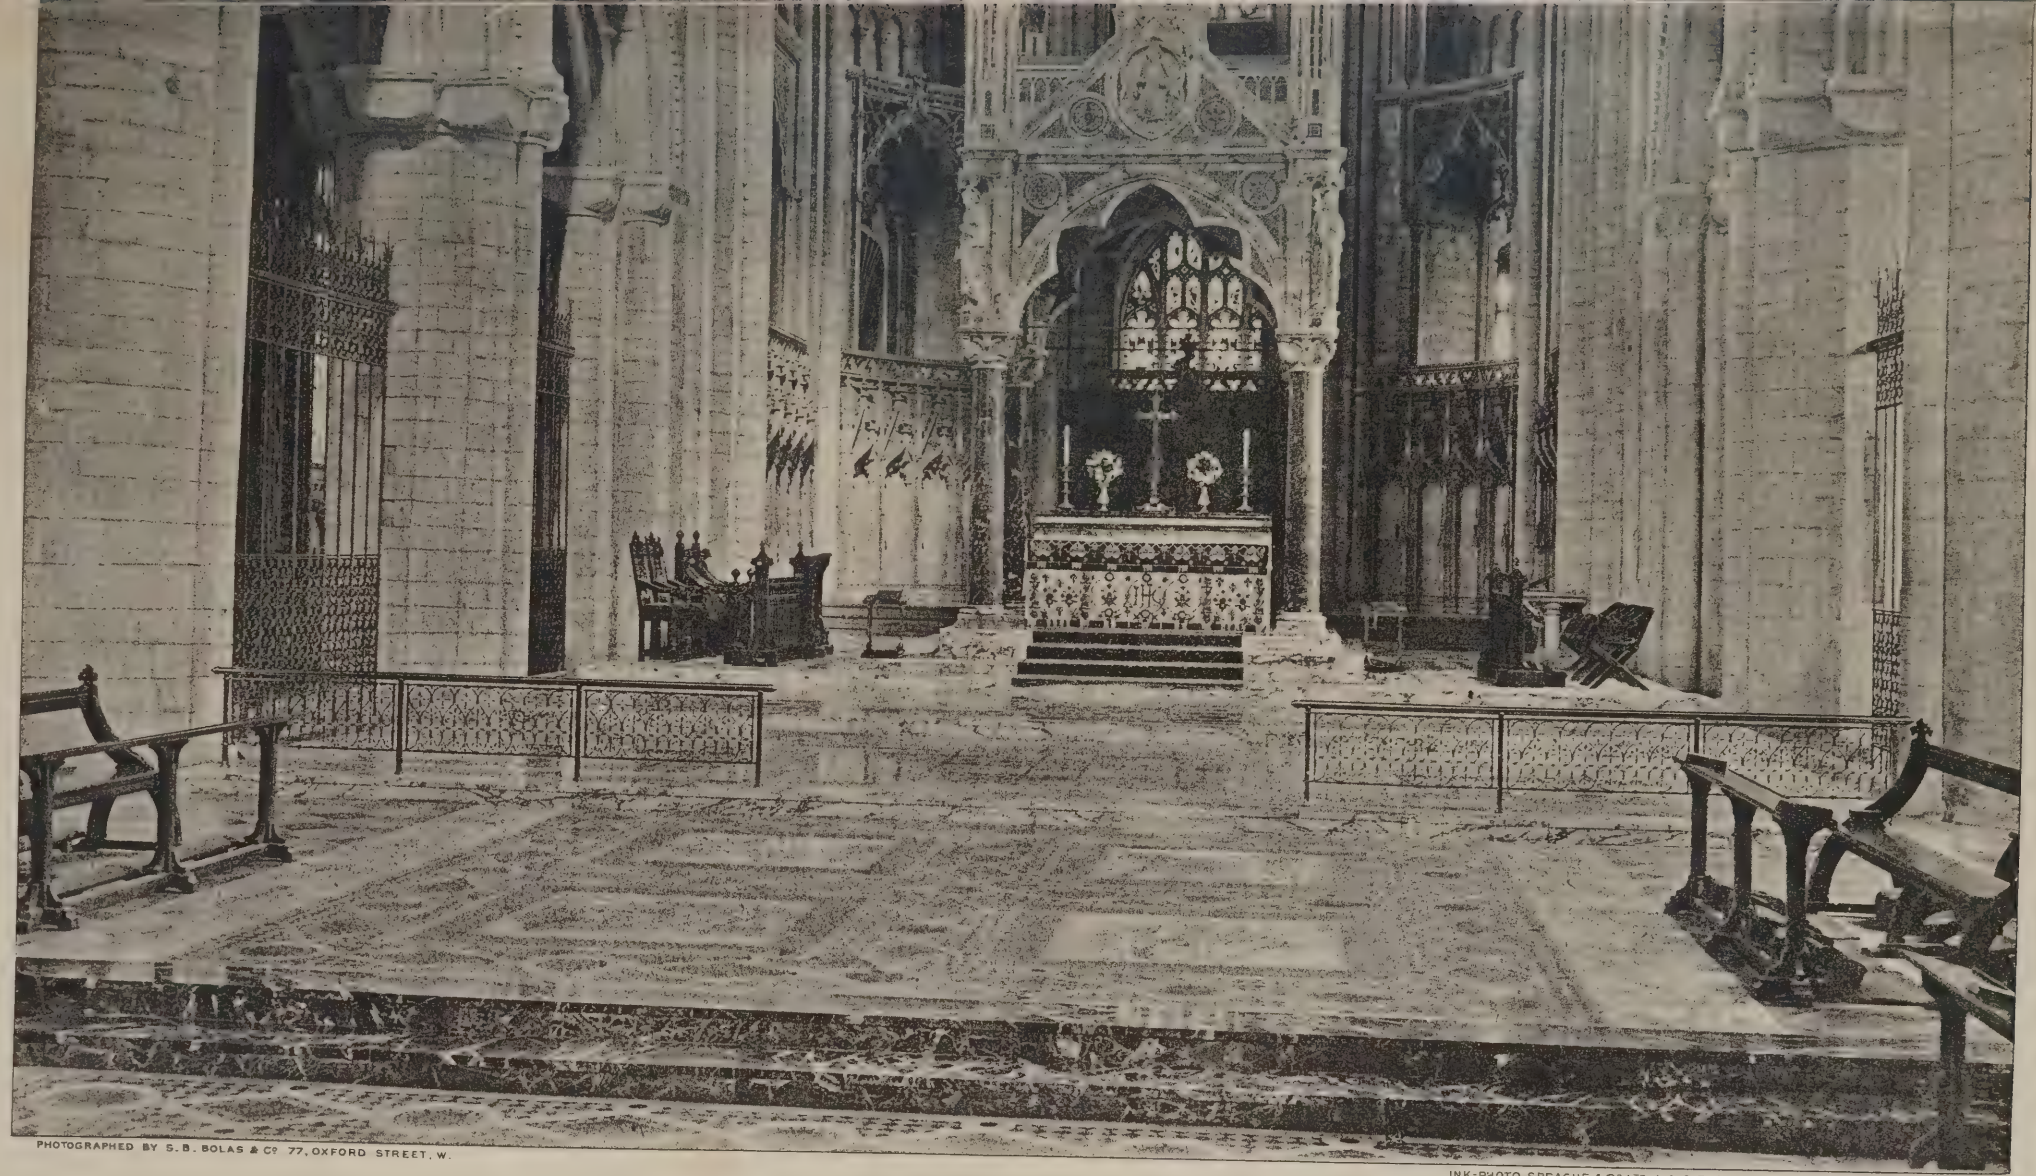
16454. Henry Boddy, for "Improvements in or connected with slating roofs."

16527. C. Kite & C. F. Kite, for "An improved inlet ventilator."

22315. Black, for "Brick-making and other moulding machines."



3464. Briggs, for "Ventilator."



To Inventors.—Patents for Inventions, Trade-marks and Designs secured; every assistance given to inventors. Specialists in Building matters. Information free.—Messrs. Rayner & Co., Patent Agents, 37 Chancery Lane, London, W.C.

MAW & CO. will forward their Pattern Books, or Special Designs, with Estimates for every kind of Wall and Floor Tiling, on application. Patterns can also be seen and particulars obtained at the Showrooms of their appointed Agents,

The Architect.

THE WEEK.

In his address at the grave of Charles Garnier M. Larroumet strove to do justice to the importance of the Opera House as an example of architecture. He said he did not believe that since the time when the Palace of Versailles was erected so fine a programme was proposed. In the building Charles Garnier created not only something corresponding with himself, but a symbol of the Second Empire and the civilisation of the nineteenth century, with its luxury, love of pleasure and affection for art. He desired that his theatre should be an example of polychrome and gilding, constructed of the richest materials, appearing immense from its proportions, and worthy to celebrate the *fêtes* that Paris was to give to all the world. In order to allow access to an interior where the most complete and the most sumptuous form of art, the lyrical drama, should display its forms, colours and masses, and pour out on all torrents of light and of tones, he created the staircase as an approach for the brilliant hierarchy of Paris as well as of all the world. It was one of those propylæa where humanity could take part in its own apotheosis, and exult in its victory over barbarism. M. Larroumet testified to the tenderness of Charles Garnier and to his gaiety and patience while suffering pain. The greatest writers and artists of the time were his friends, and many survived to deplore the loss of one of those good men who were rarely met with. M. Normand and M. Roussy, on behalf of the French architects, testified to the loss of their brother artist.

The holidays have scarcely commenced when "The Curriculum" of the Architectural Association appears. The next session begins with the annual general meeting on October 7, and the classes open three days afterwards. Members have now advantages which were denied to their predecessors. Systematic instruction is available on all the subjects with which it is necessary for a young architect to be acquainted. With a staff of teachers like Messrs. Adams, Buckman, Clarke, Collard, Farrow, Hart, Hulme, Leaning, Lewis, Pomeroy, Ransom, Satchell, Smith and Weedon, besides a body of visitors, the organisation for imparting knowledge relating to architecture as an art, science and profession is the most complete in the country. English self-reliance is shown throughout the arrangements, and we hope students will co-operate in making the classes a success. It may be added that the Discussion Section has an attractive syllabus, with such subjects as Church Restoration, Modern Architectural Tendencies, the Architect's Library, Santa Sophia, Buildings for Secondary Education, Furniture, Factory Design, Heraldry, Colour, Arbitration, the Contract System and Houses of the Speculative Type.

The following papers will be read at the ordinary general meetings of the Association:—"Excavations at Thebes," by Mr. J. E. Newberry; "Arts and Crafts," by Mr. H. Wilson; "Oriel and Bay Windows," by Mr. Paul Waterhouse, M.A.; "House-planning from the Æsthetic Point of View," by Mr. H. H. Statham; "The Position of Architecture among the Arts," by Mr. Edwin T. Hall; "Ancient and Modern Buildings in Palestine," by Mr. Beresford Pite; "Stained Glass," by Mr. Christopher Whall; "Colour Decoration," by Mr. Cole A. Adams; "Public Baths," by Mr. A. Saxon Snell; "Reflections on the English Renaissance," by Mr. Reginald T. Blomfield; "Modelling as applied to Architecture," by Mr. F. W. Pomeroy; "Specifications," by Mr. F. W. Macey; "Soil and Aspect in Relation to the Dwelling-house," by Dr. G. V. Poore.

A great many of the Paris theatres are now closed, but the Commission having charge of them is busily engaged in devising precautions against fires. Lighting arrangements, communications between different parts of the house, and the exits and entrances are all scrutinised. There is already a code of regulations, but every year some changes are introduced. This year, for example, there are additional restrictions placed on ladies' hats. They have not become more dangerous, but if the general convenience is aided few masculine theatre-goers will complain if the law has been stretched a little beyond the original intention.

On September 21 an Anglican cross 20 feet high will be unveiled at Whitby. It is a memorial of Cædmon, the earliest known Anglo-Saxon poet. We say known, for from what the venerable Bede says, Cædmon became a poet through the suffering he underwent at his inferiority to other peasants. "He was so much less instructed," says Bede, "than most of his equals that he had not even learned any poetry, so that he was frequently obliged to retire in order to hide his shame when the harp was moved towards him in the hall, where at supper it was customary for each person to sing in turn." On one of those occasions he fell asleep, and he dreamt that a stranger came to him and ordered him to sing. "What must I sing," said the cowherd, and he was ordered to sing "The Creation." His first attempt begins in this way, "Nu we sceolan herian heofonrices weard, metodes mihte," &c., which in modern English would run to this effect:—"Now we shall praise the guardian of heaven, the might of the creator and his counsel, the glory-father of men." It is very remarkable to find a predecessor of Milton in the seventh century. The nine lines which form the opening of the song of "Creation" are to be inscribed on the cross in English, Runic and Saxon characters. The memorial cross is to resemble those which were set up in Cædmon's time, and the shaft will be adorned with emblems and symbols. Through the exertions of Canon Rawnsley, of Keswick, there is at present a deficiency of only 70*l.*, and that sum will not long be wanting.

Lambeth Palace Library will be closed for the usual recess for six weeks, from August 27. There have been some interesting accessions lately on local and Kentish church history—among them we may name the history of Orpington by Rev. Chenevix Trench, a treatise on the stained-glass in Canterbury Cathedral, and another on the fine church of Minster in Sheppey. This ancient and historic structure is graphically described in Charles Dickens's "Old Curiosity Shop," and a memorial of the Queen's Jubilee, a stained-glass window representing Queen Sexburga, the foundress of this Abbey church, was unveiled in January last.

The British Consul reports that the famous theatre of La Scala, in Milan, has remained closed this season owing to the refusal of the City Council to continue the annual subsidy of about 8,000*l.* It has, however, been shown that so many important interests and industries are dependent on the maintenance of Milan's position as a great theatrical centre as to justify the granting of a subsidy. A movement is now on foot with the object of making certain reforms in the system of management, and it is very likely that the Council will reconsider its previous decision and will vote, if not the whole sum hitherto contributed, at least sufficient money to enable the theatre to be reopened next season.

At the coming meeting of the British Association Mr. E. W. Brabrook, F.S.A., will preside over the Anthropological section. Subjects relating to China and Eastern Asia generally will be considered. Papers relating to American peoples will be submitted, and the final report of the committee on the North-West tribes of Canada will be laid before the Association. Mr. C. H. Read, of the British Museum, will give an illustrated account of the treasures secured by the expedition to Benin. British archæology will be represented by reports on the lake village of Glastonbury and on the Roman city of Silchester. Professor Lloyd Morgan will read a paper on the prehistoric antiquities of the neighbourhood. An account of the first three Egyptian dynasties in the light of recent excavations, by Professor Flinders Petrie, will also be given. The proceedings of the section promise to be interesting.

HEINRICH HEINE ON FRENCH PAINTING.

By a Correspondent.

IN the week which follows the closing of Parliament, where laws are made, and of the Courts of Justice, where they are enforced, work in London becomes trying to the strongest. The town appears to be covered with a weight that is as oppressive as the fog which is to take its place in the course of a few months. All the powers which usually incite men to action become enfeebled. Who can be ambitious when a heat wave is making the blood stagnant, or can believe in the healing, the salutary influence of labour when one is pining for the luxury of lying supine for a few days or hours in some quiet spot where breezes are as beneficent as angels? That was Brunel's luxury, and as he reposed he watched the motion of a paper kite. At such a time it is a little consoling to think of those who, in "populous city pent," have had also to toil year after year without any hope of respite and nepenthe. Prominent among them must be named Heinrich Heine.

By birth Heine was a child of the Ghetto. Philistines considered he should have been thankful for the privilege of living in an *appartement* in a large and broad street, instead of amidst the sights and sounds and stenches to which his race were doomed throughout Europe. Then, too, as a soldier of liberty, as one of the forlorn hope who fought and were wounded in the struggle for reform, Heine's place was among crowds. In one of his fits of despair he imagined he could not hope to escape from the badges of infamy which were the heritage of his people, and that he was to wear one which would make him an outcast in Jewry. He became a pensioner of the French court, and that degradation made residence in Paris indispensable, for what advantage could be gained from a man living in the pine forests and who loved to watch sunrises and sunsets from the top of a mountain? Before he took to his mattress grave, with its years of continuous agony, Heine was unable to leave Paris. She might be to him a stony-hearted stepmother, but at least she afforded him protection and gave him bread. "I am exiled," he said, "in France, banished into strange speech," and the longer he lived in that condition the more his spirit was longing for the quiet German villages, a cottage with a thatched roof, homely fare and the eternal silence of the mountains.

If his desires were gratified and suitable residence were provided for him in the Herz district, and all apprehension about money removed, Heine would probably remain unsatisfied. It was his destiny apparently to be always seeking after something which, for him at least, was unattainable. The more he was disappointed, the more his expectations grew stronger. He could hardly hope that some of his wishes were ever to be gratified. When, for instance, he prayed for the straw-roofed cottage with flowers blooming around his windows and a beautiful tree in front of the door, he must surely have known it was never possible to see nature improved by the addition of six or seven of his adversaries hanging from the branches. It was the bitter contests in towns which made Heine decline to pardon enemies until they were duly executed before his eyes, in order to avoid mistakes in identification and the confounding of the innocent with the guilty. If his better nature which found delight in space uncultivated by man were properly developed, he would have rivalled Wordsworth.

Which of the two Heines attempted to describe the Salon after the stormy days of July 1831? That is the subject we propose to consider. He had made no special study of the fine arts, but as a German he had taken part in the contests over æsthetics and he could not therefore write at random, trusting to the impression which a picture made on him. Heine was brutally materialistic, but he was a Jew and could not suppose that man was no more than any of the beasts around him. Consequently he declared himself to be a supernaturalist in art. The artist cannot, he said, find all his types in nature; the most significant for him are those he discovers within himself. To show the error which was then in vogue, he referred to the theories of architecture which were based on the supposition of a resemblance between buildings, pine groves and grottos. Heine loved forests and rocks as much as any poet, and sometimes he imparted to them properties which were believed to belong to men alone. But he could not suppose the architectural types were found there; they were rather, he asserted, emanations of the mind and nothing less:—"Sie lagen nicht in der äussern Natur, sondern in der menschlichen Seele." Tones, words, colours and forms were, he considered, only symbols of ideas which arise in the mind of the artist, and the greatest artist was he who, with the fewest and simplest symbols, was able to express whatever was most significant.

In the words we have a faint suggestion of the longing after the ideal which was expressed in the old days by the desire to have the wings of a dove in order to flee from everyday life and be at rest. But another side of Jewish character was revealed when he spoke of the significance of the Dutch cabinet pictures as historic documents. When we have before us, he wrote, the pretty works (hübschen Gemälde) of Mieris, Netscher, Jan Steen, Van Dow, Van der Werff, &c., we have revealed the spirit of their time; we see, as it were, the seventeenth century before our window, we can watch the business going on and the costumes. The latter are unusually interesting, for they seem a combination of Dutch comfort with Spanish "grandezza" with the men, while with the women we have a sort of international caprice mingled with native phlegm. The good man of the house may appear smoking a clay pipe while clad in a cloak of Burgundy satin, and his wife seems to be the original of a figure in a Venetian atlas, with her Brussels lace, ostrich feathers, Russian furs and Turkish slippers. She holds an Andalusian mandolin or a foreign hound, and the Moorish page, the Turkish tapestry, the coloured parrots, the strange flowers, the great gold and silver vessels almost restless with their arabesque decoration, impart to the homely life of Holland some of the glamour of an Oriental fairy tale. Among the men and women who were the subjects of paintings in which care was lavished on details were, of course, many Hebrews, and for their sake Heine could not help loving the works. He also would have liked to be surrounded with luxuries of many colours and derived from many climes, but he was forced to be content with such vulgar surroundings as landladies allowed him.

Heine's morbid sensitiveness soon made him the most bitter of scoffers, for in no other way was he able to make people afraid of him, and careful to avoid the simplest chaffing. Sarcasm ran from his pen almost without intention. He was, therefore, a dangerous critic of pictures, books and men. But when he made his *début* in the Salon of 1831—it was then held in the Louvre—his first thoughts were full of pity. To him the majority of the thousand pictures appeared to resemble a crowd of poor folks awaiting a distribution of alms. They mutely appealed for homes to shelter them, moving his soul, as he said, like orphans who were helpless, or youth in rags. But he could not bestow even a glance of recognition on them. Heine's system was to select a few of the most prominent masters' works and give all the attention to them that was possible. For the vast mass of pictures he had no hope that any recommendation of his would bring purchasers from Germany. Painting was, like everything else, a token of a world that was out of joint. For centuries the Church was, he said, a mother to artists, but in 1831 it was as poor and helpless as the artists. Heine was also in a dubious relation to the Romanticism of the time. He was not always consistent in dealing with it, and in 1831 he thought he was justified in describing it as one of the causes which operated against the sale of pictures. Every artist was, he said, encouraged to follow his own inclinations, and to be different from everybody else, and from the indifference to rule many works were therefore despised. It is strange to find Heine an enemy to individuality, but his instincts as a representative of a family engaged in business were no doubt opposed to indifference to the needs of a market.

The painters whose works were singled out for consideration were Ary Scheffer, Horace Vernet, Eugene Delacroix, Decamps, Lessore, Schnetz, Paul Delaroche and Leopold Robert. Most of the works described by Heine were afterwards engraved on a large scale, and his judgments about form and composition can therefore be tested.

Scheffer often selected a scene from "Faust" for a subject. To the Salon of 1831 he contributed separate

figures of FAUST and MARGARET. It was said of the artist that he employed only snuff and the green soap common in Paris as materials in painting. HEINE did not accept the assertion as always descriptive, and he considered there were times when for men who were out of sorts green soap was a suitable colour. FAUST was a "Menschenruine," and to suggest what was in his brain and heart it would be useless to paint him as if formed of ivory. As for GRETCHEN, the artist had shown her as a painted soul, and when I looked at her, said HEINE, I could not help exclaiming "Liebes Kind!" the most endearing of German expressions. There was no MEPHISTOPHELES, but a substitute was found in SCHEFFER'S portrait of TALLEYRAND, for whose deceitful mask the green soap was almost too good—something more dangerous and characterless would have been more suitable. But SCHEFFER'S group of children appeared to HEINE as a party of gnomes.

HORACE VERNET about that time was turning his experience of Algiers to account in painting Biblical scenes. His works of that class merit respect, for they initiated the treatment which Mr. HOLMAN HUNT and other English artists have zealously followed. VERNET revealed the advantage of setting aside the conventionalities of the Italian masters. In the Salon of 1831 he displayed his *Judith and Holofernes*. HEINE was glad to see the Jewish woman was made so attractive; but then the sleeping warrior was also a "bon enfant," and appeared happy. As if in anticipation of his own long-drawn ending, the poet prayed that he might die as HOLOFERNES, happy in success, and suddenly, without torture and sickness, find dissolution at the hand of the being who was to him an angel of beauty. Who has not pity for CAMILLE DESMOULINS? The fate of the light-hearted journalist compelled ROBESPIERRE to weep bitter tears, and CARLYLE has shown almost as much sympathy with him as with JOHN STERLING. HEINE could be considered as a successor of him. He therefore bestowed much praise on the picture which VERNET exhibited in which poor CAMILLE was shown standing on one of the benches of the Palais-Royal, haranguing against the tyranny of the monarchy. But the critic was compelled to pass over the greater number of VERNET'S pictures. He paints everything, said HEINE, sacred pictures, battle scenes, still-life, animals, landscapes, portraits, whatever is of the moment; indeed, he is almost a pamphleteer. The conclusion was characteristic of HEINE'S way of summing up a diatribe in one word.

DELACROIX can never be a favourite with the multitude. He was too fond of merely indicating a thought, leaving the spectator to realise it in all its fulness. But for that reason his works have a fascination for men like HEINE who cannot be exhaustive of a subject. The picture of DELACROIX which conquered HEINE was the *28th July—Liberty Guiding the People*, and sometimes known as the *Barricade*. The event celebrated was too recent for the critics to consider it with unbiassed judgments. It was supposed to be evidence of the painter's renunciation of Bonapartism and of adhesion to the new dynasty. To HEINE it expressed the ambition of his life—his wish to see Liberty standing on the ruins of the various German thrones.

It is remarkable, however, that the painter who made HEINE forget he was a judge who was to decide the worth of pictures was not DELACROIX but DECAMPS. He declared he was powerless to assess the merit of works which seemed to echo the voice of his heart in tones of colour, or rather to play on his heart strings as if they were a lyre. The testimony is remarkable. We suppose DECAMPS'S love of Eastern scenes corresponded with HEINE'S, and as the poet was unable to travel beyond Europe the pictures served as a substitute. The painter at the time did not receive his meed of praise from the critics, and the injustice was another bond of union with DECAMPS.

LESSORE'S *Invalid Brother* moved HEINE, who was strong in family affection, and he commended it for not overstepping the modesty of nature and expressing much by a few strokes. SCHNETZ'S picture of *Italians at a Shrine* was praised for its technique, but it was considered to be too declamatory for acceptance as a masterpiece.

There was no artist exhibiting in 1831 who gained more success than LEOPOLD ROBERT, whose end a few years afterwards was so melancholy. In the Salon appeared his *Italian Reapers*, which now unhappily looks very faded on the walls of the Louvre, but in those days was a most brilliant picture. It represents a large harvest waggon drawn by buffaloes surrounded by peasants of the Campagna, some of whom dance and play, but all are about to become silent in order to listen to an improvisation of the poet of the party. HEINE did not hesitate to compare the work with RAPHAEL'S, especially on account of the architecturesque beauty displayed in the grouping. The difference between the two artists he considered to arise mainly from their relations to Catholicity. RAPHAEL, according to HEINE, was intoxicated with the spirit of that religion, while ROBERT, as became a Frenchman, could only look at it historically as an extinct power to which the cathedral of Notre Dame de Paris was owing.

That the Three Days and the tricolour were not able to force the French people to forget the past evidently puzzled HEINE. He was able to count at least thirty paintings in the Salon which were no more than illustrations of the romances of Sir WALTER SCOTT. The chief of the historical school at the time was PAUL DELAROCHE, who was described by HEINE as caring nothing about the past except, of course, as a treasury of subjects for representation. The first of the four pictures which the artist contributed was *Cinq Mars and De Thou as Prisoners following the Galley of Richelieu*. As HEINE remarked, two galleys in a procession form an inartistic conception, but the treatment offered amends. He admired the skill shown by DELAROCHE in making the Rhone glow with the rays of the setting sun, as a sort of prelude to the darkness which was soon to envelop the youths who conspired on behalf of the king against the more powerful cardinal. A companion scene was the *Death-bed of Mazarin*, with the groups of courtiers in gorgeous attire, who appeared to be gambling for the minister's life. It is amusing to find HEINE characteristically interrupting the current of his criticism to inform the reader of his personal interest in one of the games, for he notes how "on the right side three cavaliers and a lady are playing cards, apparently 'Landsknecht,' a very good game which I have played in Göttingen, and on one occasion won six thalers." DELAROCHE also derived from English history two subjects. One was *The Princes in the Tower*, in which the boy king and his brother were shown seated on a bed, while their spaniel barks near the door against the approaching murderers. Nothing could be simpler or more effective. HEINE was pained by the picture, for the eyes of the princes recalled to him a Polish friend and his sister. One was shot as a revolutionist; the lady was also dead, and the castle wherein he met them was in ruins. "We all vanish quickly out of the world," says HEINE, "and the stage on which we were seen also disappears, as if everything was no more than a dream." The last picture of DELAROCHE which he noted represented the meditation of CROMWELL over the coffin in which CHARLES I. was at rest. HEINE compares the English with the French king who was also executed, and he gives the preference to the former. LOUIS XVI. had ceased to be king before he was condemned, but CHARLES believed in the divine right to the last, and was a martyr. "Let us drop a tear," says HEINE, "over LUDWIG CAPET, but place a laurel on KARL STUART." Then he draws a contrast between CROMWELL and NAPOLEON, which ends in favour of the Englishman, who was considered by HEINE to be comparable to some great oak with branches extending over Britain, beneath which all could repose in peace. But the critic was brought back to the Englishmen of 1831, who were not admired by him, through the remark addressed to him by a British visitor, who was also contemplating DELAROCHE'S painting, "Do you not think, sir, that the guillotine is a great improvement?" And then his thoughts wandered over the history of modern Europe and its revolutions, which were less successful in most places than in Paris, and HEINE considered how art had also its revolutions which were not always victorious. The art of the time must, he thought, be overthrown. It was inspired by the Ancien Régime, and it would have to give way to another variety that would be created by men who were active politicians. ÆSCHYLUS fought against the Persians at Marathon who were to be described in his tragedy, and DANTE'S "Divine Comedy" is a protest against the tyranny which he had encountered in

the Florentine Council Chamber. Heine could console himself with the reflection that he had prepared himself to be one of the new creators.

The criticism on art of Heine is like all his other efforts. It is mainly inspired by egoism. That, however, is a quality which is generally successful in literature. A reader likes to meet with a writer who has confidence in sympathy, and is not afraid to expose his weakness as well as his strength. Associations were easily revived in Heine's thoughts by the sight of pictures, and his criticisms were, therefore, to some extent autobiographies. But he knew that the judging of pictures and statues was not his vocation. Heine could not be impartial when a picture recalled some of the few happy incidents in his life, or when he imagined the artist was like himself—a revolutionist. On that account, however, it is that what he wrote about exhibitions is deserving of more consideration than the articles have received. The pictures described may have faded or disappeared, but the thoughts of Heine can never cease to be interesting, wayward as they often are.

SOUTH KENSINGTON AGAIN.

THE select committee appointed to consider the subject of Museums of the Science and Art Department found it necessary to interrupt the course of their inquiry by preparing a report and supplement upon the dangerous condition of the South Kensington Museum. The report that was issued a few days back is therefore called the second, but in reality it is the first which treats of the inquiry with any completeness. We have already reprinted the most important parts of the evidence on which it is based, and have commented on what was said by the witnesses; but it is well to have authoritative conclusions from gentlemen who have considered museums from the statesman's standpoint, and are therefore more likely to be impartial than those who have suffered inconvenience from the peculiar administration which so long has been allowed to exist at South Kensington.

The Secretary of the Department, after the manner of civil servants when they apprehend the coming of changes, said there was no necessity for the reforms, and it was not desirable to introduce any modification in the organisation of the administration. We wonder he did not go further, and like the fool who appeared in the dock at one time make an application for the arrest of the judges who were to try him. He will, however, have the gratification of knowing that the foreign rivals of English production will agree with him. They want no modifications of the administration, for that highly paid body has served their interests, and they would prefer to see art and science as represented by the Department remain in its present ineffective condition. They would, however, agree that if a similar condition of affairs arose in any country on the Continent, disagreeable measures would be adopted in order to satisfy the natural desire for justice against those who have created abuses which are injurious to the State.

If tested by the standard of the ordinary Circumlocution Office the Department must be considered as wanting in the requisites for business purposes. In most Government offices very little knowledge is needed to carry on the daily duties. At South Kensington special attainments are or should be required in addition to what should be possessed by the assistants in public offices. Those attainments are rarely found. As Mr. Norman Macleod, who was once assistant secretary, confessed, "The high officers at South Kensington are not necessarily acquainted with science or art beyond having a general acquaintance with the subject." To what that general acquaintance can lead would be best described in a book on unintentional humour or in a history of human stupidity. But bounce is made to do duty for knowledge, and a South Kensington official becomes to his admirers an Admirable Crichton. It is very hard to discover what he can do which a man of business would approve. Accounts, for instance, cannot be properly kept at South Kensington. The report tells us it is quite impossible to separate the cost of the Museum from that of the Department. The magic sign "&c." is used abundantly, and it is always evidence of expenditure which cannot be ascertained. For example, a sum of 26,000*l.* is put down for "attendants, messengers, repairers, labellers, printers, store assistants, cleaners, &c.," but nothing is stated about the numbers employed, or the officials or work which "&c." can designate. In another place 5,600*l.* is entered for furniture, materials, &c., and Bethnal Green is charged elsewhere with 6,800*l.* for "furniture, materials, &c., and fitting up objects for exhibition." Yet with all this outlay show-cases have had to be lent from South Kensington to Bethnal Green. The laxity of the Department becomes more discreditable to the officials if the accounts are compared with those of the British Museum, which might be prepared in a City office. Then, again, in a period of five years ending December 31, 1897, a sum of 4,600*l.* was voted for "historical collection of oil and water-colours." But according to the accounts the sum expended was 8,256*l.* Where did the difference come from? The Admirable Crichtons did not, we suppose, contribute the money. But the "&c." covers a multitude of deficiencies on both the debit and credit sides of the South Kensington ledgers. The committee say:—"The explanation given is scarcely adequate, unless the word '&c.' appended to water-colours and other drawings be considered a sufficient explanation for an expenditure exceeding receipts by nearly 50 per cent."

In such investigations as that into Museums it is an advantage to consider the draft report, although it may not be adopted in its entirety. In the draft prepared by Lord Balcarres the Admirable Crichtons are described as "shuffling officials." His lordship's opinion of their value to the State is as follows:—

> It is obvious that the Museum has suffered from a lack of experts. The Secretary of the Department told the committee that unless the South Kensington staff be trebled or quadrupled, it is not possible to have specialists. With this opinion we entirely disagree. Sir Edward Maunde Thompson, the head official of the British Museum, pointed out that expertise is not necessarily gained by having a large staff, but that it can be, and at the British Museum is, gained by a careful selection of young men for the subordinate posts, and, having selected them, limiting their work to a single department of art or archæology. Thus in the coin and medal department, out of a total staff of five, two officials are experts of international repute, and the remainder are also considered experts. Similarly, in the large department of prints and drawings, the officials possess the highest expert knowledge. This is attributed by Sir Edward Maunde Thompson to the fact that young men are placed in a department and remain working there; they are not moved from one branch of work to another. At South Kensington this process of shuffling is frequent. An official cannot be "moved from the Art Library to the Art Museum"; but he can be (and frequently is) moved from the custody of art objects to the custody of art books. We are strongly of opinion that this shuffling of officials is detrimental to the public service. Thus one junior assistant has served in Circulation, Art Library and India Museum—and, of course, has become an "all round man." Another passed from the accounts division into the India Museum, whence he was transferred to the Art Library. It is almost impossible for the "all round man" to become an expert in archæology, bibliography, or art.

There cannot be a better test of the inefficiency of the officials, whether considered as shufflers, all round men or superior beings, than the catalogues. The majority of visitors naturally conclude they are the compositions of officials. It will scarcely be credited that, according to the committee's report, "the Museum does not appear to have any catalogue or guide of its own except a small fly-sheet issued last year, which is distributed gratis." The familiar sixpenny guide with the red cover "is private property, belonging to the heirs of an official actually employed in the Department." The handbooks and portfolios of views are private ventures. Yet somehow the unlucky taxpayer will find he has had to take a share in the ventures without having the least chance of profit. A catalogue of national portraits cost between 620*l.* and 880*l.* Considerable sums of public money have been expended on catalogues which are incomplete or not worth printing. The committee recommend that "the Department should have undivided control of these publications and that these commercial undertakings should be withdrawn." The catalogues reveal the illicit businesses that have grown around the Department and which it will be found most difficult to suppress.

Reform is also required in the labels. When we find a description of this kind attached to an object—"One of 94

pieces of Gothic architectural design, chiefly of oak, consisting of panels, friezes, pilasters, &c., English, Flemish, &c.; 15th and 16th centuries; average dimensions 20 inches by 12 "—we must believe the label-writer was resolved to avoid interfering with the "private venture" of the catalogue projector. There is so much of the same sort of respect for commercial speculations, the committee recommend "that until the objects in the Museum are accurately labelled, all energy should be concentrated on this work, the primary requirement."

But then arises the question, How many objects are not worth the trouble of labelling? According to the report, "a judicious elimination of the worthless things" is called for, but who is to decide about the extent of the operation? When one reads of 71*l.* 8*s.* being paid for a vase, while two identical vases which cost only 9*l.* 10*s.* for the pair were in the Museum, the infallibility of the experts is not undoubted. A Cingalese chair of the eighteenth century was acquired in the belief it once held the portly presence of Cardinal WOLSEY. An artist now on the staff of the Museum composed a cabinet out of "bits," and the authorities paid 816*l.* for it. An agate cup, worth 50*l.* as a modern "make-up," was acquired by the outlay of 535*l.* The Bethnal Green Museum has been utilised as a refuge for many of those curiosities of official connoisseurism, and we hope they have afforded lessons on dishonest dealings. We expected the committee to announce whatever was known about the origin of the costly shams which, after a course of testing, became public property. But in connection with South Kensington an exhibition of courageous plain speaking is dangerous, and the committee content themselves with saying:—"On the question of who were the persons responsible for recommending the purchase of objects proved or alleged to be spurious, we prefer to express no opinion, and we decline to enter into the discussion of circumstances which many years ago attended the purchase, or negotiations for purchase, of certain objects, concerning which much conflicting evidence was brought before us."

As a rule the officials appeared to be as contented with the system as the birds which are to be seen under the authority of a cat in a happy family exhibition. One could not allow himself to be hypnotised with fear, and Mr. WEALE's fate will convince the minor officials that silence is the best policy when departmental errors are in question. We must say the committee have shown as little courage in dealing with the case of the keeper of the Art Library as with that of the spurious objects. They say:—"Your committee desire to record their opinion that the termination of the engagement of Mr. WEALE, late keeper of the Art Library, immediately after the rising of the House in 1897, and subsequent to the giving of evidence by Mr. WEALE, in which errors and abuses of administration in the Museum were freely exposed, very much resembles a breach of privilege and an infringement of the immunity usually enjoyed by witnesses before committees of the House of Commons."

Who could have believed that the guarded words are all that could be discovered to brand the authors of an act that in another period would have called forth the power of the House of Commons? It was not in that hesitating style the original draft was expressed. There it was stated that Mr. WEALE is "the only living man out of the large staff of the Science and Art Department who has an international reputation;" that he reduced the Art Library from chaos to order; that his diligence and fidelity were officially recognised. But it was admitted that the evidence he gave before the committee "must have been distasteful to the authorities, because he ruthlessly exposed the folly and abuses of the present system; in fact, when asked a question he answered it fully and without reserve." Mr. WEALE had reached the limit of age prescribed for officials. But the Treasury wished his services should be retained as long as the inquiry into the Museums was going on. A week after Parliament had risen, and when no question could be asked in the House of Commons, the Department dismissed "a man of European distinction as if he were an ordinary wage-earner." The draft report says:—"Only one conclusion can be drawn from a perusal of the documents, an irresistible conclusion that the nature of Mr. WEALE's evidence was the sole cause of his dismissal. His evidence was most damning, but this was already provided for; and notwithstanding his invaluable services to the library, his 'diligence' and his 'fidelity,' Mr. WEALE was duly punished. We have no doubt that the Department claims 'technical' rectitude for its action. There is no doubt that the Department when inaccurate, and even when resorting to subterfuge, is invariably 'technically right.'" And it concludes with the following words, which express the opinion of many of those who as outsiders are acquainted with the defects of the institution:—"Is it not time that those in authority should try to cleanse the 'bad name' attaching to South Kensington? For years the Department has been the nest of these sordid personal controversies: it has been honeycombed with nepotism and there have been serious monetary defalcations. Even now there are financial questions which demand the immediate attention of the Treasury. Laughable errors will be gladly overlooked by the public if some assurance be given that a serious effort will be made to raise its tone and to purify its administration."

It does not help the cause of reform when passages like the foregoing are, as the Americans say, "whittled down" in order to make things as pleasant as possible all round. The best proof of their truth is that the recommendations of the committee are mainly confined to maladministration. As a rule Parliamentary committees suggest additional expenditure on the Department that comes under their attention. But the committee on Museums is an exception. It was necessary to recommend rebuilding the South Kensington Museum, but otherwise the demands on the Exchequer are comparatively trivial. It will need no additional outlay to make the primary function of the Director for Art the supervision of art schools and classes, or put upon the Director of the Art Museum the sole responsibility for all purchases. The abolition of the Art Referees is a saving, and it is absurd for a dozen gentlemen of high standing to be paid four guineas apiece for considering the suitability of some trifling object for the Museum. A separate staff for the Art Library would not necessarily increase the expense. The recommendation to avoid spending large sums in describing such prints as "Mr. WEST, wax-chandler and oilman of Soho," is also a move to economy, although it is not often such a bibliographical curiosity is attainable as the catalogue of "National Engraved Portraits," compiled by a cousin of the secretary at the modest rate of two guineas a day. In it PUGIN is described as "cruising about the Channel in quest of archæological and natural curiosities." Humour is a costly production, but from 600*l.* to 800*l.* is rather a high price to pay for official jokes of that kind. To exhibit somebody's soap and hair washes as "technological specimens" is almost as entertaining, although not involving outlay.

One item of expenditure that is suggested is the employment of a clerk of works at 3*l.* or 4*l.* a week, in order to relieve General FESTING of the heavy burden of looking after bricklayers when occasionally employed in repairs to furnaces and boilers. The Works Department is said to be organised on a faulty basis, but that is true of every one of the departments and of the Science and Art Department itself. The Bethnal Green Museum, which has cost 132,000*l.* to maintain, was described by one witness as only suitable for a playground and resting-place for children. When there was an exhibition of furniture held in it, the Department did not bring out the catalogue until two months after the closing. The only recommendation the committee can offer is to hand over the white elephant to the County Council. The committee desire to see the Geological Museum in Jermyn Street restricted to British geological specimens. The Edinburgh Museum is said to suffer from the centralising tendency of South Kensington, and it is recommended that a greater power of initiative should be allowed to the director, and as much is said about the direction in Dublin. In connection with the Dublin Museum, the necessity of an herbarium is recognised. It is proposed to expend the money saved by abandoning the Bethnal Green Museum on establishing a museum in Wales. Finally it is proposed, as a means to rehabilitate the prestige of South Kensington and overcome the prejudice in the public mind, to appoint a Board of Visitors who would advise the Lord President upon questions connected with the arrangement, management, cataloguing and classification of collections, and also

with regard to loans, purchases, elimination and exchange.

The appalling thought that comes from reading the report is that the revelations arise out of the management of the South Kensington Museum which, with its countless deficiencies, is, however, the least unsatisfactory product of the Departmental system. If a similar inquiry into the operations of the South Kensington officials in connection with the teaching of science and art and the other divisions which have been seized were ordered by the House of Commons, who would be able to imagine the exposure that must follow? Yet until the evils are laid bare it will be impossible to attain the reforms that are demanded or to "cleanse the bad name attaching to South Kensington."

THE WHITE HORSE OF BERKSHIRE.

ONCE more the people of the Vale have undertaken the periodic process of "The Scouring of the White Horse," which the late Judge Hughes made the subject of an interesting book. Archæologists differ about the origin and purpose of what is probably the largest representation of an animal in existence, and which, owing to the interest taken in it, is never likely to be obliterated. The following paper by the late Mr. W. J. Thoms will suggest the various theories which have been brought forward to explain the object of the work :—

The remarkable monument of antiquity which gives its name to the Vale of White Horse in Berkshire has not, I believe, attracted the particular attention of any antiquary since 1738, when the Rev. Francis Wise published his "Letter to Dr. Mead, concerning some Antiquities in Berkshire," &c.; or, perhaps I should rather say, since 1742, the date of his second work upon the subject, entitled "Further Observations upon the White Horse and other Antiquities in Berkshire," &c.

From the silence of Leland, and the slight mention which Camden (who only notices it incidentally) has made of the White Horse, many have been inclined to doubt whether the figure possesses any claim to great antiquity. These doubts are, however, totally groundless.

Wise has proved that the Vale of White Horse was known by that name in the forty-second of Edward III. (1368-69), by a reference to an entry upon the Close Rolls for that year, in which it is recorded that "Gerard de l'Isle tient en la Vale de White Horse 1 fee," and I am enabled to adduce evidence that the White Horse was in existence so early as the reign of Henry II. The proof is contained in two valuable cartularies of the abbey of Abingdon, now preserved in the British Museum. In one of these is the following entry relating to Sparsholt :—

"Prope Montem, ubi ad album equum scanditur, ab antiquo tempore Ecclesia ista manerium Offentun appellatum in dominio possidet, juxta quod Villa x. hidarum adjacet ex jure ecclesie quam Spereshol nominavit. Hunc miles, Anskillus nomine, de ecclesia tempore Rainaldi abbatis pro unius militis servitio tenebat. Verum hunc contigit et ipsius abbatis regisque junioris Willelmi inimicitias adeo incurrisse postea, ut in regia poneretur captione ibique moriretur."

This carries back the known and acknowledged existence of the White Horse to the reign of Richard I., for such is the date of the volume from which it is extracted; while by the other cartulary, which was written in the reign of Henry II., in 1171 or soon after, it is ascertained that the hill on which it is figured bore the name of White Horse Hill at a yet earlier period. The following is the passage in question :—

"Consuetudinis apud Anglos tunc erat, ut Monachi qui vellent pecuniarum patrimoniorumque forent susceptibiles, ipsisque fruentes quomodo placeret dispensarent. Unde et in Abbendonia duo, Leofricus et Godricus Cild appellati, quorum unus, Godricus, Spersholt juxta locum qui vulgo Mons Albi Equi nuncupatur, alter Leofricus Hwitceorce super flumen Tamisie maneria sita patrimoniali jure obtinebant. Quorum unum, id est Spersholt, usque hodie ecclesie feudo remansit, aliud vero Wigodus oppidanorum Walingafordensium dominus possedit, velle Monachorum predictorum hinc et inde de eisdem terris sic se referente. Hec accidisset de una secus quam de altera, si viro secundum morem gentis necdum austeriora edocto ferre remissius blandiretur; domno Adelelmo abbate dominatum loci hujus obtinente."

Aldelm was abbot of Abingdon from 1072 to 1084.

In the face of such historical testimony to the existence of this remarkable monument soon after the Norman Conquest, there can be little hesitation in pronouncing it the production of a far earlier period.

Mr. Wise is of opinion, and he maintains that opinion with considerable learning and ingenuity, that the White Horse is a monument of the West Saxons, made in memory of a great victory obtained by Alfred over the Danes in 871; while the object of the present communication is to show the probability that it is commemorative of the ancient religion of the country. Nor can this opinion be considered very unreasonable when it is remembered that the worship of the horse was common to the Celtic and Germanic, as well as the Sclavonic tribes.

The work may consequently be even of British origin; and when we consider the resemblance which the figure of the horse bears to that which is exhibited on some of the coins now admitted by our best numismatists to be the coinage of the ancient Britons, it will scarcely be matter of surprise should this remarkable monument find antiquaries disposed to contend for its Celtic origin. That it may be so, and as such commemorative of the mythic horse of the Britons, is certainly possible, but the far greater probability is that it refers to the "sacred horses," which form so important an object in the mythological system of our Saxon forefathers and other people of the Germanic race.

From these sacred horses it is probable that many of the ancient heroes derived their names, of which Hengist and Horsa furnish a striking example, those names being nearly synonymous, although the former, Hengist or Hengst, is in the German and some other of the Teutonic tongues more particularly applied to stallions.

The important position which the horses of the gods assume in the mythological poems of the north is a point, too, which on the present occasion cannot be passed over in silence. Sleipnir, the eight-footed horse of Odin, is of these the most important; and it is a very remarkable fact, in connection with the present inquiry, as showing for how long a time after the introduction of Christianity the memory of this mythic steed was preserved in the popular customs and observances of the people, that until a comparatively recent period, at least as lately as the sixteenth century, it was a custom in Mecklenburg, at the conclusion of harvest, to leave in the fields some small portion of the earth's produce as an offering to Woden and as fodder for his horse; the reapers shouting at the conclusion of their labours—

> Woden, bring your horse now fodder,
> Now thistle and thorn,
> Another year, better corn.

I think I have met with an allusion to a similar custom in this country, although I cannot now refer to it.

The truth of that striking and often quoted passage from the "De Moribus Germanorum" of Tacitus, which Mr. Wise has already adduced to show that the Germans consecrated woods and groves, and were accustomed to regard the warnings and auguries of horses, for which purpose white horses were kept in such hallowed groves, and never desecrated by being put to any kind of labour, receives abundant confirmation from later writers.

One of the most remarkable instances is quoted by Grimm in his "Deutsche Mythologie" from one of the Northern Saga, the Saga of Olaf Trygvesson. Grimm quotes from the rare edition of 1689-90, and notices with regret that the chapter from which his quotation is taken is omitted in some of the later editions of the work. The account is as follows :—

"Olaf having been informed that the inhabitants of Drontheim had relapsed into the worship of Freyr, he commanded them to destroy the statue of Freyr which was still remaining among them. This they refused to do. Whereupon Olaf summoned an assembly of them, and having determined that he himself would destroy the idol, sailed to that part of the coast where stood the temple of Freyr. When he landed he found the sacred horses of the god depasturing in its precincts. The king instantly mounted the stallion, and permitting his courtiers to take the mares, they thus rode to the temple. On arriving there Olaf overthrew the idols, and took away with him the statue of Freyr.

"When the people found how their gods had been put to shame, and how the image of Freyr had been removed, they well knew that it was the act of the king, and attended the meeting to which he had summoned them. The king, having placed Freyr's image in the midst of the assembled people, demanded of them, 'Know ye this man?' They answered, 'It is Freyr, our god.' 'How has he proved his power to you?' inquired Olaf. 'He has ofttimes spoken with us, prophesied unto us coming events, and bestowed upon us peace and plenty.' 'It was the devil who spake with you,' said the king, and, taking up an axe, he called out to the idol, 'Now help yourself, defend yourself if you can.' But Freyr remaining silent Olaf smote off both his hands, and then preached to the people and exhorted them to renounce their idolatry."

This story bears in many points so remarkable a resemblance to the narrative which Beda has left us of the profanation of the heathen temple at Godmundham, in Yorkshire, by Coiffi, the high priest, when Edwin and his chief friends and counsellors were converted to Christianity by the preaching of Paulinus, that it is scarcely too much to believe that we have recorded in these two instances the form of procedure adopted in all cases for the desecration of the temples of heathenism.

I quote Beda's narrative from the English version edited by

Dr. Giles, and can hardly help suspecting that the stallion on which Coiffi rode was one of the sacred horses attached to the temple, and not one of the king's, as Beda relates. Coiffi is described as having, after hearing Paulinus, advised the king "to set fire to the temples and altars, which we have consecrated without reaping any benefit from them." In short, the king publicly gave his license to Paulinus to preach the Gospel, and, renouncing idolatry, declared that he received the faith of Christ; and when he inquired of the high priest who should first profane the altars and temples of their idols, with the enclosures that were about them, he answered, "I; for who can more properly than myself destroy those things which I worshipped through ignorance, for an example to all others, through the wisdom which has been given me by the true God!" Then immediately, in contempt of his former superstitions, he desired the king to furnish him with arms and a stallion, and, mounting the same, he set out to destroy the idols, for it was not lawful before for the high priest either to carry arms or to ride on any but a mare. Having, therefore, girt a sword about him, with a spear in his hand, he mounted the king's stallion and proceeded to the idols. The multitude beholding it concluded he was distracted, but he lost no time, for as soon as he drew near the temple he profaned the same, casting into it the spear which he held, and rejoicing in the knowledge of the worship of the true God, he commanded his companions to detroy the temple, with all its enclosures, by fire.

But to proceed. It may be said, first, that admitting that the Saxons were accustomed to keep such sacred horses within the groves by which their temples were surrounded, what proof have we that any Saxon temple stood in the neighbourhood of the remarkable figure now under consideration? And, secondly, even though the existence of such temple be established, what connection can there have been between it and the figure in question?

To the first I answer, that the extensive downs on which this extraordinary monument is found were formerly remarkable for the groves of ash trees with which they were covered, and the memory of which is preserved in the name of the parish of Ashbury (which, as Wise has already proved, was formerly called Ashdown), and in those of other localities in the neighbourhood.

Wise, when speaking on this point, observes: "Near Letcombe is a shrubby place still called The Ashes, and Letcombe Ashes; where, as I have been informed by a curious and learned gentleman of this neighbourhood, grew, within the memory of several persons lately dead, abundance of tall and very fine ashes."

Now the ash, it must be remembered, was reckoned by the Saxons among the sacred trees, being regarded by them with a veneration almost, if not altogether, equal to that which they paid to the oak. Nor is this to be wondered at, when we bear in mind that in the Edda, the Voluspa and many other of those literary remains of the North to which we are indebted for all we know of the mythological system of our ancestors, the ash tree, Yggdrassil, is repeatedly spoken of as "the most sacred tree of the gods;" "the tree under which the gods sate in judgment;" as "the tree from which the first man was formed."

It is clear, then, that the ash was reverenced by our Saxon forefathers; and when Plot, in his history of Staffordshire, tells us "the common people believe that it is very dangerous to break a bough from the ash to this very day," he proves that this feeling of veneration was not then extinguished among us.

Taking, therefore, these various circumstances into consideration, I am inclined to believe that the White Horse of Berkshire is no monument commemorative of victory, but a memorial formed by the Saxons, at the time of their conversion to Christianity, of the sacred white horse, which in the days of Paganism had depastured in the sacred grove of ashes, and I am confirmed in this opinion by the recollection that this monument is not a solitary one, but that several others of similar character are still existing in the country.

Since writing the above, I have been favoured by Mr. Akerman with the subjoined letter, in which (confirming my anticipation) he expresses his belief that the White Horse is of Celtic origin.

"I am not disposed to subscribe to the popular tradition that these figures are of Saxon origin. We all know that the horse was a favourite Saxon and Anglo-Saxon badge, and, indeed, their national symbol; but it is equally certain that it was also a favourite one with the Celtic tribes. It is a constantly occurring type of the Gaulish and British coins, which, though modelled on those of civilised states, appear to be accommodated to the tastes and feelings of the people who adopted them. Although thus modelled and accommodated, the religious motive of the type appears to me to be no less obvious. It would, therefore, seem highly probable that while Caligula was contemplating the raising his horse to the consulship, the Britons, Gauls and Germans were paying divine honours to this noble animal.

"The Marquis de Lagoy, a very sound and able antiquary, has published a coin of the Belindi, a people of Aquitaine, mentioned by Pliny, on the reverse of which is a horse, not galloping, as usually represented on the Gaulish and British money, but standing within a distyle temple. The learned Marquis supposes that this figure represents the goddess Epona, mentioned by Apuleius, and, if the conjecture be no allowed, it cannot be doubted that the Gauls worshipped some divinity under that form, a fact of which the coin in question is the sole but authentic evidence."

SCIENCE AND ART EXHIBITIONS.

WE have received from the Department of Science and Art the following list of candidates to whom Royal exhibitions (art) and local scholarships (art) have been awarded for 1898:—To Royal exhibitions—William R. S. Stott, 19, art student, Aberdeen, Gray's; Charles G. Lowther, 18, art student, Hull; John M. Aiken, 18, art student, Aberdeen, Gray's; Septimus E. Scott, 19, art student, Royal College of Art; Herbert Slinger, 22, art student, Bradford, Technical College; Thomas Jones, 23, art student, Royal College of Art; Percival H. Portsmouth, 23, art student, Reading; Ada Erwood, 22, art pupil teacher, Brighton; Frank Nowill, 24, draughtsman, Sheffield, and John E. Sutcliffe, 22, art student, Royal College of Art. To local scholarships—George E. Kruger, 17, art student, Bath; William H. Helm, 19, art student, Royal College of Art; Janet M. G. Brennand, 21, art student, Bournemouth (West); Frank H. Round, 18, art student, Birmingham; Leonard T. Howells, 20, art student, Lydney; Arthur W. Pope, 20, art student, Nottingham; Edwin A. Morrow, 21, house decorator, Belfast; Harold Wilson, 19, art student, Birmingham; Isabella McGregor, 21, art student, Royal College of Art; James Durden, 20, art student, Royal College of Art; Alfred Bentley, 19, art student, Bristol, Merchant Venturers; Walter W. Igglesden, 21, art student, Torquay; Gertrude M. Siddall, 21, art pupil teacher, Chester; Gordon M. Forsyth, 18, glass stainer, Aberdeen, Gray's; James Sparks, 21, art student, Bristol, Queen's Road; Alexander McN. S. Richardson, 20, art pupil teacher, Dundee, Technical Institute; and Henry T. Pike, 21, art student, Southampton, Hartley Institution.

MALMESBURY ABBEY.

THE Bishop of Bristol has held a conference with the vicar and churchwardens of Malmesbury and the mayor of the borough on the subject of the abbey church. The unanimous opinion was that the ancient fabric must be taken in hand without delay. The work naturally divided itself into three heads—(1) To make quite sound the fabric of the six bays of the nave which form the parish church; (2) to make the interior more dignified as a place of worship; and (3) to protect the ruined parts as far as possible from further decay. There was an agreement of opinion at the conference against proposing to undertake two other works which have often been suggested, namely (4) To build out a chancel to the east, and (5) to rebuild the three western bays of the nave. The Bishop, who is a vice-president of the Society of Antiquaries, has undertaken to obtain a preliminary survey of the fabric from an antiquarian point of view, to be followed eventually by a complete report.

PLAYING-CARD DESIGNS.

THE Worshipful Company of Makers of Playing Cards offers the H. D. Phillips Prize of 5*l.* 5*s.* for the best special design for the backs of playing-cards, intended for presentation by the company to its guests at the banquet of the master and wardens in November next. Two other prizes of 3*l.* 3*s.* and 2*l.* 2*s.* respectively are offered by the company for the two next best of such designs. The designs must be of the size of an ordinary playing-card, and are to be in colour, and such as can be reproduced effectively in not more than six printings. The arms of the company are to form a portion of the design. Designs must be sent to W. Hayes, the clerk of the company, Guildhall, London, E.C., not later than September 27 next. The monogram or device of the artist is to be marked on the back of each design and on the outside of a sealed envelope to accompany it, within which envelope must be given the full name and address of the artist. The three designs selected are to be the absolute property of the company; the unselected ones will be returned to the senders. Novelty of design will be regarded as an important element in the competition

NOTES AND COMMENTS.

A competition for two appointments as inspecting architects of historic monuments will take place in Paris on March 1 next year. The jury will consist of several of the inspectors-general, viz. M.M. Lisch, Selmersheim, Bœswillwald, De Baudot, Vaudremer, Daumet, with M. André, the conservator of sculpture in the Louvre. All the competitors will have to present evidence of an analytic study of ancient buildings with plans of some modern works of theirs. The Minister of Fine Arts will select a certain number to undergo examination; each will have to present plans and studies of some building erected between the eleventh and sixteenth centuries, with a scheme of restoration, accompanied by a specification and an estimate. The building selected must be one which will display the aptitude of the competitor for dealing with all classes of construction. There will also be an oral examination, for a part of which the project submitted will form the basis. The candidate will, in addition, be questioned closely about his knowledge of the history of art, archæology, the use of materials, construction and accounts. What we have said will show the care which is taken to obtain the services of competent officers for restorations.

The museums of the University of Cambridge are not in a satisfactory condition. The collections illustrative of geology, botany and zoology have become too extensive for the accommodation provided. The recently erected buildings for the department of mechanism have proved insufficient for the growth of the school, and the need for another lecture-room and more laboratory space has become pressing. The buildings devoted to medicine and surgery are not only in a bad state of repair, but are also inadequate and inconvenient. The presents of specimens during the past year have been numerous, and so much interest is taken by graduates in the university, there is no doubt that many other valuable examples would be forthcoming if there was a certainty that space could be found for them.

According to Mr. Harold Frederic, the young Queen of the Netherlands at her approaching coronation and assumption of regal authority will be richer in jewels, plate, furniture and rare works of art than it was imagined she would be. Many years before she was born her father, Willem III., brought to Holland an operatic celebrity, with whom he had become fascinated in Paris, and installed her at the Château Loo with a genial effrontery of publicity at which the Dutch gorge rose. Both the court at The Hague and public opinion were so hostile that she had to be sent back to Paris. As the price of her retirement without fuss she extorted from him permission to loot all the royal palaces and public museums and collections, and carry off the things she fancied most to furnish the mansion he had taken for her near the Champs-Elysées. It was years before the full extent of her immense depredations was discovered by the Dutch officials. Characteristically they said nothing, but kept a steadfast eye on the lady. She died recently, and when her effects came up for sale at the Hôtel Drouot the Baron von Zuylen was on hand and quietly bought up all that the Dutch Government wished to reclaim. Among the carloads of treasures thus returning to Holland are a great many heirlooms of the Orange family, as well as objects of historical interest.

Architects who aspire to be connected with country workhouses will find a knowledge of agriculture and horticulture to be advantageous. Here, for example, is the programme which has been prepared by the Steyning Board of Guardians for dealing with the new workhouse grounds, and which the architect will have to realise to the best of his ability:—(1) That the garden should be cultivated for the sole use of the inmates, only selling the surplus; (2) that the ground be divided into three portions; (3) that twelve acres be appropriated for producing green vegetables and potatoes for the inmates; (4) that two acres be used as a kitchen garden for the master's and staff's use, and also for growing the small culinary vegetables for the house; (5) that the rest be laid down as a recreation-ground, viz. that part which was nearest to the new buildings about to be constructed; (6) that the whole be enclosed by a 9-inch brick wall with unclimbable coping, a space for entrance being left at the lower end; (7) that a 10-foot road be made from north to south, dividing the whole up to the recreation ground into two equal portions; (8) that the master be empowered to employ two or three men to get the rubbish chopped down before cultivating; (9) that the whole shall be ploughed by steam as soon as possible; (10) that the architect set out at once where the new road comes and mark off the twelve acres and the two acres of kitchen garden; (11) that a 1½-inch water main be connected to the workhouse supply pipe, continuing down the road to the pig pounds and tapped at intervals; (12) that a range of ten pig pounds be erected at the lower end of the ground in order that the large quantity of wash from the house may be utilised; (13) that as soon as the stables are erected a suitable horse be kept to go in the van and fill up its time in the garden; and (14) that the committee be given power to hire horses and implements for cultivating the ground, buying seeds and other necessary articles for the purpose, and that a requisition book be kept by the master for the above purpose. It is no wonder one of the Guardians considered the work was "a tall order," but the architect is not likely to object to the arrangements.

ILLUSTRATIONS.

CATHEDRAL SERIES.—PETERBOROUGH: NAVE, LOOKING EAST. DOORWAY IN CLOISTERS. TOP OF CENTRAL GABLE, WEST FRONT.

WINTHORPE, EPSOM.

THIS house has been built for Mr. R. Gee in the Ashley Road, Epsom. It occupies a fine position overlooking "The Durdans," half-way up the road leading to the top of Epsom Downs. It is faced with good red-brick facings with Bath stone dressings and tiled with Broseley tiles.

Ground Floor Plan.

Scale of feet

The top floor contains a very fine billiard-room with an organ chamber at the turret end. The works have been carried out under the supervision and to plans prepared by Mr. Edward Carter, A.R.I.B.A., of 55 Clarence Street, Kingston-on-Thames. A wing has been recently added containing breakfast-room and conservatory, under the supervision of Messrs. Carter & Ashworth, of 55 Clarence Street, Kingston-on-Thames, and 8 Duke Street, Adelphi, W.C.

DESIGN FOR PROPOSED JUBILEE CLOCK TOWER, LEWISHAM.

APARTMENT HOUSE IN THE CHAMPS-ELYSEES, PARIS.

PALLADIO.

THE "Raphael of architects," Andrea Palladio, was born at Vicenza A.D. 1508, on November 30, St. Andrew's Day, whence the choice of his Christian name. His earliest application was to sculpture, but, having the good fortune to attract the notice of his illustrious townsman, Count John George Trissino, who discovered his natural propensity to mathematical science, he was by his new patron directed to the reading of Euclid, Vitruvius and Alberti, and afterwards taken by him thrice to Rome, where he diligently measured and designed the choicest remains of ancient architecture. He visited Rome a fourth time in consequence of a call to employment in the fabric of St. Peter; but finding on his arrival there the Pope dead, and all things in confusion, he made no other advantage of that journey than to review and remeasure those relics of Roman magnificence he had before examined and admired. He further corrected his measures and designs in a fifth journey to that capital in company of some Venetian gentlemen, his friends. About this time he printed a little book on those antiquities, usually joined to that entituled "Mirabilia Romæ." Thus diligently prepared he at his return entered vigorously on practice with the most advantageous offers of employment in his own country and out of it. At twenty-nine years of age he was entrusted with the conduct of the public palace at Udinè, called Il Castello, begun by John Fontana. Near the same time he planned and directed the execution of the porticos enclosing on three sides the great Hall of Justice at Vicenza, a work of which he speaks (B. III. c. xx. of his "Architecture") with more consciousness of his success than he has upon any other occasion discovered. He was invited by the Cardinal of Trent to build his palace in that city; by Emanuel Filibert, Duke of Savoy, on the same account; by the city of Bologna, for the front of the great church of St. Petronio, for which he made four different designs; by Brescia for the rebuilding the public palace there, nearly destroyed by fire. The Republic of Venice, his natural sovereign, both pensioned and employed him after the death of Sansovino on all occasions. In Vicenza and its neighbourhood he left ample proof of his superior taste and skill in a great variety of houses, villas, churches and other public buildings. The designs of most of these he has inserted in his well-known book of architecture. It is observable, however, that those who have taken his measures from the actual fabrics, and compared them with what are set down in the designs there given, have found many differences of proportion, but if these are not improvements as to effect, it has not been noticed that they are prejudicial to it.

Palladio is generally believed to have had a fifth book of his "Architecture" nearly ready for the press when he died, containing designs of ancient temples, arches, sepulchres, baths, &c., which, with his other unpublished plans and writings, he left to his particular friend, the Senator Giacomo Contarini (no mean judge of that art), upon whose demise they were all dispersed. Some were collected by the Earl of Burlington during his travels and printed with great magnificence at his own expense. It is highly probable that many of those scattered designs were executed in different places at different intervals after Palladio's death with no other indication of their author than what their manner must afford the discerning observer. It is not, therefore, always safe to deny him the credit of an invention, the style should warrant his, because the date of the execution is posterior to his decease.

He was particularly curious in whatever related to the art of war as practised by the ancients, and laboured much in the explanation of Polybius and Cæsar, by plans and discourses. His elucidations of the former author were dedicated to Francis, the reigning Grand Duke of Tuscany. Those of the latter are printed with Baldelli's Italian translation of the "Commentaries." It is certain that the profound erudition of his friend Trissino assisted him greatly in the study of the Roman art of war; and thence, by mistake, might arise the tradition of the same friend having been his master in architecture likewise. Palladio explained many difficulties in Vitruvius to D. Barbaro, and furnished him the drawings that accompany his Italian translation of that author with a commentary.

The last great effort of Palladio's genius was the design of the Olympic Theatre in Vicenza, begun May 23, 1580, by an Academy of that name instituted in 1555, of which he was a member and had been one of the first promoters. In this work he meant to realise his own idea of the ancient theatres, as derived from Vitruvius and the remaining Roman structures of that kind, but he lived not to conduct it further that a part of the foundations. His surviving son Silla was appointed to the superintendence upon his decease, and Scamozzi directed the standing scenes. The completed fabric was viewed by the best judges of the time with rapturous admiration, and has ever since been reputed by some enthusiasts to be a prodigy of the art in a country where its wonders are not rare even to the critical eye. Its form differs from that of the ancient models in being a half ellipse instead of a semicircle. This change was an accommodation to site, no little contributive to the merit of the whole invention.

Palladio is described as rather low of stature, of a pleasing countenance, cheerful and open in conversation, but ever observant of his superiors in rank or knowledge; fond of the society of men of letters, and well able to bear his part in discourse with them. In the exercise of his profession he is said to have been communicative and engaging to his workmen, without descending to a familiarity derogatory from the respect they owed him.

Beside his surviving son Silla, he had Leonidas, bred an architect likewise, and Horatio, who applied to law. Both these died young, within three months one of the other. Their untimely loss he laments in his dissertation on the Roman militia, prefixed to the above mentioned translation of Cæsar's "Commentaries." His own death happened on August 19, 1580, aged seventy-two, at Vicenza, where he was buried, with the usual honours of a superior artist, in the church of the Santa Corona, of the Dominicans.

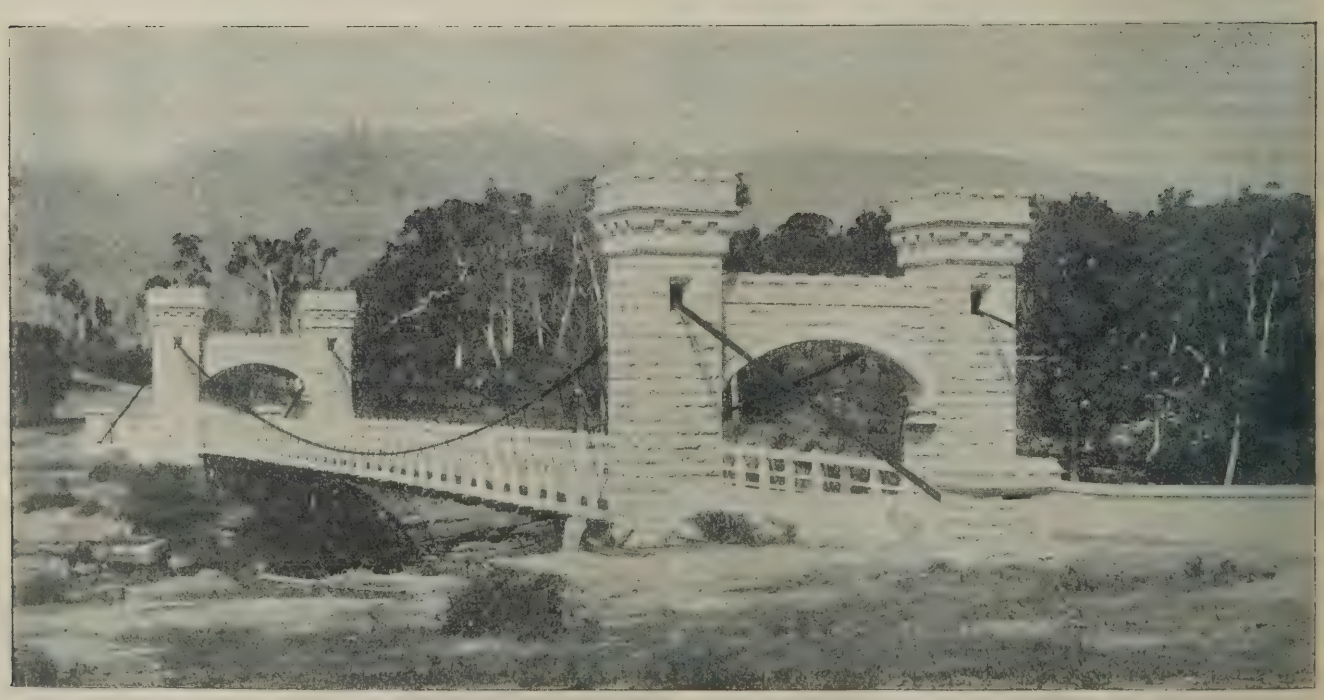
Among the numerous Italian architects of the sixteenth century, fruitful in genius of every kind, pre-eminence is, by the joint suffrages of his countrymen and of foreigners, assigned to Palladio. A perfect acquaintance with the literature and sciences subservient to his art, a profound study of the ancient models, and a quick perception of whatever contributes to the greatness of effect that distinguishes them, conspired to advance his natural aptitude for his profession to excellence. Not content to measure and design the edifices of antiquity as a matter of form, he traced them to their foundations, examined their grosser materials, and the various modes of combining them as conducive to strength or reductive of expense. In the superintendence of his own works he was particularly attentive to the manual execution.

If we examine his peculiar style, his greater buildings have an air of grandeur that seems to be the result of volume, proportion and ornament, dictated by propriety. His villas speak themselves the retreats of nobility, veiled but not hid. If analogy between the human and material fabrics (much resorted to by writers on architecture) be allowable here, perhaps we may not unfitly say that the general effect of Palladio's edifices is similar to that of personal dignity well dressed. In a word, the perfection of his whole manner has occasioned him to be called the Raphael of architects.

Of the buildings ascribed to him not in his book are, in Venice, the church of St. Giorgio Maggiore, the refectory and other pieces of the monastery—front of that St. Francesco della Vigna, built by Sansovino—del Redemtore alla Zuecca de' Cappucini—delle Zitelle—di St. Lucia—some repairs of the Ducal Palace. At Vicenza Santa Maria Nuova—Palazzo Prefettizio, his name on the east front—façade of the Palazzo Tornieri—that of the Pal. del Conte L. Schio—a house of his design supposed for himself, but which it appears he could have occupied only as a renter—Arco delle Scale del Monte, from the manner thought to be a design of his—Doric Loggia and a door, in the garden of the Counts Valmarana—two rustic doors in the garden of Count Porto. In Padua, nel Borgo di Santa Croce, a house of singular contrivance, for the conveniences it includes in small area. In Bologna, northern front and Court of Pal. Ruini, since Ranucci. In Parma, part of the theatre, carried on by Bernini, Spada and Magnani.

DERBYSHIRE ARCHÆOLOGICAL AND NATURAL HISTORY SOCIETY.

A PARTY of about forty members of this Society paid a visit on the 10th inst. to Bolsover Castle and Hardwicke Hall. They left Derby at 11.10 A.M. in two first-class saloons provided by the Midland Railway Company, and on arriving at Chesterfield dined at the Old Angel Inn. At one o'clock brakes took them to Bolsover, where the Rev. C. Kerry, editor of the Society's magazine, briefly reviewed the history of the place. The drive was then resumed to Hardwick, and a very pleasant hour was spent at the hall, the Rev. C. Kerry giving a short history of the life of the Lady Arabella Stuart. Tea was partaken of at the Hardwick Inn, and the drive back to Chesterfield was much enjoyed. The weather before midday was wretched, but before the party left Chesterfield there was a break in the clouds and the afternoon turned out unexpectedly pleasant. The arrangements were admirably made by Mr. Arthur Cox, of Mill Hill, Derby, the hon. secretary of the Society, and amongst those who took part in the excursion were the Hon. F. Strutt, the Revs. C. H. Leacroft and R. G Burton, Councillor J. Walker, Mr. G. Sutherland, &c.



The Fiftieth Annual Meeting of the Somersetshire Archæological and Natural History Society will be held at Taunton on August 30 and three following days, under the presidency of Mr. E. J. Stanley, M.P. Exeter Cathedral will be visited on September 1.

PUBLIC WORKS IN NEW SOUTH WALES.

MOST of the bridges in New South Wales have been constructed by the Public Works Department of that colony, combining the essentials of utility, durability and economy in a most commendable manner, especially to those providing the loan moneys, with the assistance of which the completion of such structures is effected. The most recent of these works is a suspension bridge across Kangaroo Valley, about 107 miles south of Sydney, and forming portion of the mail route, by way of the Fitzroy Falls, between the great southern line and the coast. The road, which is much frequented by tourists, begins three miles after leaving the falls, a descent of about 2,000 feet at the Barrangarry Mountain, reaching Kangaroo Valley township, twenty-three miles below. Between the foot of Barrangarry Mountain and the valley township runs the Kangaroo Valley river, confined at the point where the road crosses it between precipitous banks 55 feet in height, and subject to floods which rise to the level of the banks.

As is generally the case with mountain rivers, a safe ford is difficult to find, save during continued dry weather, while in

flood time the river is absolutely impassable. In 1878 a wooden bridge, 250 feet in length, was thrown across the stream, but it was swept away during a heavy flood at the beginning of the present year, shortly after the new bridge, of which illustrations are given, was completed.

The suspension type was adopted with a view of placing the structure above the level of the highest possible floods; at the same time the abundance of fine sandstone in the neighbourhood enabled the masonry work to be executed in a highly finished style. The bridge has a single clear span of 252 feet, with a roadway 18 feet in width. The massive towers at each end are 55 feet in height, and with the arched openings in the roadway between them present a somewhat picturesque appearance.

The cables which, passing through openings in the upper portion of the towers, support the roadway are formed each of fourteen steel wire ropes. These ropes are each 4½ inches in circumference and capable of sustaining a breaking load of 86 tons. The total strain on each cable when the bridge is loaded is 280 tons, and to resist this strain the cables are carried down and secured in chambers cut to a depth of 24 feet in the solid rock. Stiffening trusses of iron bark timber on each side of the road supply the necessary rigidity to the structure, and on account of the long span and height above the water form a somewhat graceful outline. The bridge, by reason of the preponderance of masonry and steel in its construction, is practically permanent, though the timber roadway will at lengthened intervals need renewal—940 cubic yards of masonry and concrete.

The bridge was designed by Messrs. De Burgh & Allan, under the direction of Mr. Robert Hickson, M.Inst.C.E., Under-Secretary for Works and Commissioner for Roads, and was erected under the supervision of Mr. E. M. De Burgh, the Assistant Engineer for Bridges.

The contract was let to Messrs. Loveridge & Hudson, 63 tons of iron and steel and 4,800 tons of timber being used for the work, Mr. James Rorison acting as resident engineer for the Government.

LEON BATISTA ALBERTI ON FRESCO.

THE connecting link between ancient and revived art was Leon Batista Alberti. D'Agincourt does not hesitate to attribute the Renaissance of architecture, in a great measure, to his exertions and those of his countryman and contemporary Brunelleschi, the constructor of the Duomo of Florence. Alberti was eminent in all the arts, but attached himself principally to architecture, and applied himself with much assiduity to the study and explanation of the work of Vitruvius. His principal work, "De Re Ædificatoria," was completed and a manuscript copy presented to Pope Nicholas V. in 1452, and was printed at Florence at the early period of 1485. It contains, observes D'Agincourt, all that could be known at that time relative to the art, and, if we confess the truth, almost all that has since been written in the best works on the same subject.

Alberti treats concerning the coats of plaster which should be laid on walls, of the various kinds of intonachi and how the mortar with which they are made is to be prepared, of statues in basso-rilievo, and of the pictures with which the walls are adorned. According to him, in all plasterings three kinds, at least, of intonachi are required. The first is called rinzaffato, and its use is to adhere very closely to the wall, and to hold firmly the other two intonachi which are laid upon it. The use of the last intonaco is to receive the polish and the colours and lineaments which make the work pleasing. The use of the middle intonaco, which is now called arricciato, is to obviate any defects both in the first and in the last intonaco. The defects are as follows:—If the two last coats, namely, the arricciato and the intonaco, are caustic, and, so to speak, astringent, as rinzaffato ought to be, they will, on account of their crudity, show many cracks as they dry. And if the rinzaffato is mild, as the intonaco should be, it will not adhere sufficiently to the wall, but will fall off in pieces. The more coats of it are given, the better will the surface receive the polish, and be enabled to withstand the effects of the weather. I have seen some of the more ancient specimens which had nine coats, one upon the other. It is necessary for the first of these to be rough, containing pit sand and pounded brick, the pieces of which should not be too small, but as big as acorns, or in pieces the size of the finger, and sometimes the size of a palm. For the arricciato river sand is best, being less liable to crack; this arricciato should also be rough, because the coats which are to be laid on afterwards will not adhere to

smooth surfaces. The last coat must be very white, like marble; in fact, very white pounded stone should be used instead of sand, and it will be sufficient for this coat to be half a finger's breadth in thickness, because, if it is made too thick, it dries with difficulty. I have seen some persons who, in order to save expense, do not make this coat thicker than the sole of a shoe. The arricciato must be mixed according as it is nearer to the first or to the second coat. In the masses of stone in stone quarries there are found certain veins very much resembling transparent alabaster, which are neither marble nor gesso, but of a certain middle nature between the one and the other, and which are very apt to crumble. When these are pounded and used instead of sand, they sparkle like shining marble. In many places are seen sharp points projecting from the wall in order to hold the intonachi, and time has shown us that these are better made of bronze than of iron. I approve very much of those who, instead of nails, insert between the stones certain pieces of stone or flints so as to project; but for this purpose a wooden mallet must be used, and the fresher and rougher the wall is the better it will hold the rinzaffato, the arricciato and the intonaco; therefore if, while building, and while the work is being done, you apply the rinzaffato, although thinly, you will cause the arricciato and the intonaco to adhere to it very strongly, so as never to separate. You may carry on any of these processes during the prevalence of the south wind, but if you apply the intonaco while the north wind blows, or during severe cold or great heat, the intonaco will immediately become rough or uneven.

Finally, the last coats are of two sorts; they are either plastered and spread upon the wall, or they are composed of materials joined and fitted on to it. Gesso and lime are spread upon it, but gesso is not good except in very dry places, for the damp which passes down old walls is very injurious to every kind of coating. The coatings which are joined on to the walls are stones, glasses and such things. The coatings which are spread upon walls are these:—Pure white, with figures of stucco or paintings; but those which are joined on are wainscottings, panellings and inlaid works. We shall now speak of the first sort, for which the mortar must be prepared as follows:—

Slake the lime with clear water in a covered trough, and with so much water that there may be a great excess above the lime; then stir it well with a spade, kneading and working it thoroughly; and let it be thoroughly slaked and kneaded, which may be known by the spade not meeting with any lumps or clods. To this we must add that much water must not be added to the lime at once when slaking it; but it must be quenched a little at a time, pouring water on it at intervals until it is completely saturated; then put it in a place rather damp than otherwise, and in the shade, without mixing anything with it; for it should be preserved pure—covering it only with a little sand until, by length of time, it is become more liquid. And it has been found that, by this long maceration, the lime has acquired great virtue. I have actually seen some very ancient, and in considerable quantity, which had been abandoned—as we have good reason to suppose—for more than 500 years; and then being discovered, it was found to be moist and liquid, and, as it were, so ripe that in its consistence it far surpassed honey and marrow. And there certainly is nothing that can be found more convenient for any purpose whatever than this. If you use it thus, it requires double the quantity of sand. The lime is not considered to be mature in less than three months. That which is good must be very soft and viscid, because if the trowel put into it comes out dry, it proves that it has not had enough water to slake it completely. When you mix it with the sand, or with any powdered materials, work it again and again with great labour, and continue to work it until it almost froths. The ancients were accustomed to pound in a mortar the materials they required for the intonachi, and they tempered the mixture so that it might not adhere to the trowel when they were laying it on the wall. Upon the coat which has just been put on, and while it is still wet and soft, another coat must be laid, and care must be taken that all these coatings may dry together and at the same instant. They must be smoothed and made even with smoothing boards, floats and other similar things while they are yet soft. If the last coat of pure white be well rubbed, it will shine like a looking-glass; and if, when the same is nearly dry, you anoint it with wax and mastic, liquefied with a very little oil, and then heat the wall so anointed with a chafing dish of lighted charcoal, or with an iron, so that it may soak up the ointment, it will surpass marble in whiteness. I have found by experience that such intonachi never cracked, if in making them the moment the little cracks begin to appear they are rubbed down with bundles of twigs of the wild mallow or of wild broom. But if, on any occasion, you have to apply an intonaco in the dog days or in very hot places, pound and cut up very finely some old rope and mix it with the intonaco. Besides this, it will be very delicately polished if you throw on it a little white soap dissolved in tepid water. If it is too greasy it will become pale.

Small figures of stucco may be executed very expeditiously by casting from hollow moulds, and the hollow moulds may be obtained from rilievos by pouring liquid gesso over them. When they are dry, if they are anointed with the composition which I have mentioned, they will have a surface like marble. These figurines are of two sorts, some in entire relief, and some in bas-relief; those in high relief do very well on a flat wall, but on a vaulted roof bas-reliefs are better, because those which are in high relief, on account of their weight, being fixed obliquely, easily separate and fall down, and are likely to fall on the heads of those that are beneath. Care must be taken not to put hollow ornaments, or ornaments in high relief, where there is much dust, but let them be flat and in low relief in order to clean them easily. The painted intonachi are sometimes executed in fresco and sometimes in secco. For those which are done in fresco, all natural colours, which are obtained from the earth or from mines, or from similar places, are proper; but artificial colours, and particularly those which change when exposed to the fire, require very dry things, and dislike lime, moonshine and the south wind. It has been recently discovered that all colours can be mixed with linseed oil, and will last for ever provided that the wall upon which they are put be very dry and completely free from damp; although I find that the ancient painters were accustomed, in painting the sterns of their ships, to use liquid wax instead of glue. And, if I remember right, I have seen in the works of the ancients that factitious gems, fastened to the wall with wax, or perhaps with white stucco, become so hard in course of time that they separated neither with fire nor water. You would say that it was burnt glass; and I have seen some who, with the white flower of lime, have fastened colours, particularly vitrified colours, to the walls while still fresh.

AMERICAN LIBRARY BUILDINGS.*

NOTICEABLE is the increasing tendency on the part of library boards to recognise that the librarian himself is, or ought to be, the expert authority to be consulted within the field of technical library details. An ideal way of bringing the librarian into closest contact with every successive step in the planning and construction of the building is by making him either the secretary or a member of the committee, board or other sub-organisation of the governing body which has the immediate charge of erecting the building. Should this be done at the very outset, before even the building lot has been secured, the resulting benefit will be seen in the fact that each separate division of the general subject as it comes up will be considered, discussed and finally agreed upon in the light of the suggestions which the librarian is able to bring forward. This has been done in the case of the New York, Newark and Providence public library buildings.

Mention should be made of several architectural competitions which are of exceptional interest. The first of these is that of the New York Public Library. The preliminary arrangements were conducted by a committee of the board (with a special advisory committee of three, consisting of the executive officer of the library, Dr. Billings, Professor William R. Ware, of Columbia University, and Mr. Bernard R. Green, of the Library of Congress). It is not pleasant to be obliged to add that owing to a peculiarly unenlightened course of action which the New York City Controller has felt obliged to adopt this admirable building remains unbuilt, and not even begun. A letter from Dr. Billings, dated May 19, 1898, says:—"The matter is now before the Department of Public Parks and the Board of Estimate and Apportionment, and it is impossible to say when action will be taken. I think it probable that ultimately the necessary funds will be granted and the work go on to complete the contract made by the city, but this may not be done before next fall, or possibly not for a year."

One of the most elaborate schemes of architectural competition is that embodied in the pamphlet of thirty-nine pages, entitled "Programme for International Competition for the Phebe Hearst Architectural Plan of the University of California" (including a library building for 750,000 volumes), which is dated "Berkeley, Cal., December 3, 1897," and which was distributed to architects and others in both continents early in 1898. The estimated cost of [the building is not stated, but the fact that the sum of 50,000 dols. has been set apart simply for the purposes of this competition, including the payment of the awards, makes this a noteworthy architectural incident.

Among instances of buildings not yet begun, but now in the earliest stages of preparation, there may be named the New York State Library at Albany (now moving for a location distinct from the State Capitol), the Cleveland Public Library (now making comparison of plans), and the St. Louis Public Library (which on March 24 last purchased a lot 324 feet by 282 feet for its new building). To these should be added the New York Public Library and the Jersey City Public Library,

* From a paper by Mr. William E. Foster, librarian, Public Library, Providence, Rhode Island.

neither of which has yet advanced beyond the stage of securing plans.

Seven libraries, costing in each instance more than 100,000 dols., are now in process of construction, namely, the Lynn (Mass.) Public Library, the Fall River (Mass.) Public Library, the Providence (R.I.) Public Library, the Free Public Library, Newark, N.J.; the Wisconsin State Historical Society Library, Madison, Wis.; the Milwaukee Public Library and Museum, and the Omaha (Neb.) Public Library.

The record of noteworthy library buildings which have been opened to the public since January 1, 1895, is a striking one. It includes the Boston Public Library, January 31, 1895; the Carnegie Library, Pittsburg, November 5, 1895; the Pratt Institute Library, Brooklyn, May 26, 1896; the Peoria (Ill.) Public Library, February 11, 1897; the Hart Memorial Library, Troy, N.Y., May 12, 1897; the Kansas City Public Library, September 1, 1897; the Chicago Public Library, October 9, 1897; the Columbia University Library, October 12, 1897; the Library of Congress, November 1, 1897; and the Princeton University Library, November 7, 1897.

Several of the public libraries above named show a striking resemblance in general type of architecture. It is obviously only a superficial observation which would classify them as "reproducing" the architecture of the Boston Public Library Building. It would be more correct to say that both the Boston Public Library and the others named below show strongly the influence of the Sainte-Geneviève Library in Paris, as that, in turn, shows the influence of some of the Italian palaces of the Renaissance, such as the Pitti Palace at Florence or the Pompeii Palace at Verona.

This is a phenomenon which should possess not only interest but instructiveness for both the librarian and the architect who are studying the future of library architecture. Some of the subordinate bearings may be stated as follows:—

1. The architectural strong point of this type seems to consist in the symmetry and simplicity of its outlines; in the main two parallel lines extended horizontally only so far as symmetry demands. It does not include such a feature as a tower as one of its outgrowths, and it seems to embody the counsel of an eminent English architect, quoted in a recent paper, "If you have height, do all you can to emphasise it and make it tell," and similarly, if you have length, emphasise that. In this case it is length that is emphasised and made effective.

2. Provided the other dimensions are so pronounced as to preserve the symmetry above indicated, this is an architectural type that even lends itself well to buildings of so great a height as the Chicago Public Library. This is a building whose fenestration—practically only two horizontal lines of window spaces—gives the spectator at first no real conception of its true size, its height being 90 feet. Much the same may be said of the New York Public Library, though this is classified under another heading below.
